About the Editors

K. Bradley Penuel is the Director of the Center for Catastrophe Preparedness and Response (CCPR) at New York University (NYU) where he also serves as the assistant vice president for Health Initiatives. Additionally, in response to the recent major storm events that have effected New York State, Mr. Penuel was appointed co-chair (along with Admiral Thad Allen) by Governor Andrew Cuomo of the NYS Respond Commission to improve New York State's emergency preparedness and response capabilities and strengthen the state's infrastructure to withstand natural disasters. Previously, while with Chemonics International in Washington, D.C., Mr. Penuel consulted on initiatives for the U.S. Agency for International Development (USAID) and the World Bank. He has also served as an environmental engineer for Gresham, Smith and Partners, in Nashville, Tennessee. Mr. Penuel received a B.S. in civil engineering from Auburn University and a Master's degree in urban planning from New York University's Wagner School of Public Service. He is also the co-editor of the *Encyclopedia of Disaster Relief* (2010, with Dr. Matthew Statler).

Matt Statler is the Richman Family Director of Business Ethics and Social Impact Programming and clinical assistant professor of management and organizations at New York University (NYU) Stern School of Business. Previously, Statler served NYU's Center for Catastrophe Preparedness and Response as the director of research, and as associate director of the International Center for Enterprise Preparedness. He worked as director of research and as a research fellow at the Imagination Lab Foundation in Lausanne, Switzerland, following several years as a management consultant in New York City. His research has been published in journals such as *Leadership*, the *Journal of Business Ethics,* and *Long Range Planning*, and he is the co-editor of the *Encyclopedia of Disaster Relief* (with K. Bradley Penuel) and *Learning From the Global Financial Crisis: Creatively, Reliably, Sustainably* (with Paul Shrivastava).

Ryan Hagen is a Paul F. Lazarsfeld doctoral fellow in the Department of Sociology at Columbia University, where his research interests focus on the organizational perception and management of catastrophic risk. He has served as a research associate for New York University's Center for Catastrophe Preparedness and Response, and worked as a journalist, with articles appearing in *Slate* and the *New York Times*. He received his B.A. in English and American literature from New York University. Born and raised in Wauwatosa, Wisconsin, he now lives in New York City.

Introduction

Whenever systems break down unexpectedly, crises can arise. If the initial breakdown is not managed effectively, crises can spread over space and time to threaten not only the effective function but also the existence of the system itself. In this sense, "crisis management" involves planning for, coping with, and recovering from the impacts of unexpected events. As the scope, scale, and complexity of the systems that organize contemporary society increase, crisis management becomes increasingly critical in order to sustain everyday life.

Crisis management is relatively young, having emerged as a field of practice and a field of academic research in the late 1980s following a succession of high-profile and deadly system breakdowns (including the Bhopal gas leak, the nuclear accident in Chernobyl, the explosion of the *Challenger* space shuttle, and the *Exxon Valdez* oil spill). More recently, the crises associated with events as diverse as rogue traders, disease outbreaks, computer malfunctions, and terrorist attacks have led to the establishment of variety of subdisciplines, including business continuity management, disaster recovery, operational risk management, and enterprise risk management. In all of these cases, and in everyday personal situations, crises are "associated with urgent, high-stakes challenges in which the outcomes can vary widely … [depending] on the actions taken by those involved," as stated in the *Encyclopedia of Leadership*.

As of this writing, the most prominent high-stakes challenges currently include the financial and economic crisis that originated in the real estate market in the United States in 2008, continues to have dramatic impacts in the Eurozone, and has recently snared JPMorganChase in scandal; the political crises associated with the Arab Spring, including most recently the tragic civil unrest in Syria; and the looming ecological crisis associated with climate change, which amplified the damage done to coastal cities and towns in the northeastern United States by recent weather events, typified by Hurricane Sandy.

Effective action in response to crisis situations such as these requires art as well as science. Perhaps the most iconic image of the scientific management of crisis is the control center with digital screens along the walls displaying maps, graphs, and charts, with analysts sitting at computer terminals and commanding officers barking out orders. Such settings do exist, and they depend on a variety of networks and embedded technological systems, including everything from the information-gathering and surveillance systems that feed data into the system, to the IT infrastructures that provide a platform for those systems, to the dashboard-style decision support systems that enable leaders to make individual and collective decisions.

In addition to these concepts and resources, creativity and imagination are required in order to deal with unexpected events. Within large businesses, the military, and civil defense organizations, it has become standard practice to include artists, writers, and other creative professionals in scenario planning and war-gaming exercises for the purely tactical reason that they are able to view systems holistically, imagine alternative causal chains, and thereby identify previously unseen sources of vulnerability as well as resilience.

In order to describe and understand why some systems—and indeed, some people—appear more resilient to unexpected events than others, scholars draw on a range of academic disciplines. Computer scientists are developing ever more robust network architecture and backup systems. Natural scientists are working to better understand Earth systems to mitigate natural hazards. Social scientists are developing new ways to model risk and to understand how and why social systems break down in ways that lead to crises, as well as how to avoid these breakdowns or mitigate their consequences. Business management disciplines have formalized new approaches to maintaining operational continuity in the face of disruptions, whether they affect a single enterprise or threaten an entire industry sector, city, or region.

Within this context, the concept of "global risk management" signals a recognition that some potential crises can be addressed only through engagement across the boundaries of individual firms or industrial sectors, and across the divides between governments and the private sector. To this end, in 2006, the World Economic Forum (WEF) began issuing an annual *Global Risk Report*, outlining potential sources of common risk. For example, the WEF's 2007 report highlighted 23 global risks arranged in five categories: economic (e.g., "oil price shock," "excessive indebtedness," etc.), environmental (e.g., climate change or natural disasters), geopolitical (e.g., international terrorism), societal (e.g., pandemics or "liability regimes") and technological (e.g., failure of "critical information infrastructure," and nanotechnology). In 2011, the Organisation for Economic Co-operation and Development (OECD) released its *Future Global Shocks* report, addressing the risk of extreme events that produce continent spanning disruptions. The authors note that, especially in the wake of the 2008 financial crisis, risk management has come to focus on "drivers of vulnerability that tightly weave interconnections between commercial supply chains, technological systems and investment vehicles underlying the global economy," and that "unanticipated events such as natural disasters, failures in key technical systems or malicious attacks could disrupt these complex systems and produce shocks that propagate around the world." Furthermore, the report argues that "knowledge management tools, modeling and data arrays" are making it easier to anticipate and respond to these new cascading risks.

There have been attempts to manage global risk first hand, including efforts through the Global Risk Network (GRN), a project that emerged out of recommendations in the *9/11 Commission Report* and which ultimately found a home through New York University's Center for Catastrophe Preparedness and Response and International Center for Enterprise Preparedness. The GRN now meets regularly, bringing together crisis managers from global companies, nongovernmental organizations, and governments from around the world to build trusted networks and address shared risks.

Ultimately, we see the distinction between natural disasters and social crisis blurring. Within the last decade, there have been at least two cases during which significant natural disasters have cascaded into crises within different social and organizational systems. Hurricane Katrina in 2005 left the city of New Orleans with a local government crippled by a shrunken tax base and substantial infrastructural damage from which the city has yet to fully recover. The storm and its aftermath also triggered crises in the coordination between the Louisiana state government and various U.S. federal agencies. In 2011, the Tohoku earthquake and tsunami that devastated northeast Japan also triggered a nuclear crisis at the stricken Fukushima power station, which led to a crisis of confidence in the leadership of the Japanese government. The radiological accident also wounded the reputation of TEPCO, the company that operated the Fukushima plant, and led to a previously unthinkable shutdown of all of the country's nuclear reactors.

To some extent, the factors that contributed to these crises were well, if not also widely, known. And yet, key actors were surprised by how these systems suffered from crisis, and they were forced to take unplanned actions in hopes of reducing their negative impacts.

The 2008 financial crisis provides an excellent illustration of how the breakdown of one system can precipitate a crisis that spreads over time and throughout other interdependent systems. If a single event could be assigned causal precedence, it would perhaps be at the level of Lehman Brothers' risk management system. Their model—like the models used by many other investment firms at the time—did not adequately hedge the risks associated with mortgage-backed securities, and so when other market participants began to retreat, the firm was in too deep, overly leveraged, and without recourse. At a basic, ethical level, this event could be framed as a breakdown of trust between counterparties. It also represents a crisis of governance and oversight, both in terms of the banks' own boards of directors and in terms of government regulation of the financial markets; a crisis of professionalism, involving mortgage brokers who knowingly duped and defrauded clients; and an identity crisis within business schools, questioning the meaning and purpose of business education.

Given the complex and dynamic nature of the field, we seek in this *Encyclopedia of Crisis Management* to provide an overview of how the practices and the concepts associated with crisis management are currently evolving. In this editorial endeavor, we have presented coverage of 15 categories of articles. These articles include descriptions of agencies within the United Nations and the federal and U.S. state governments, explanations of crises in the engineering and technological sectors, financial and business groups, and natural disasters. We also delve into the crises of politics, international relations, and civil violence, as well as population and demographics. Disaster information databases are covered as well as major nongovernmental organizations, such as religious groups, the United Way, Red Cross/Red Crescent, and the Paul G. Allen Foundation. Risk management standards are included, and also numerous articles on theory, issues, and techniques—presented in civil, corporate, general, public health, and social sciences contexts. In all, some 352 articles explore crisis management in an A-to-Z format, from "Agency Notification and Mobilization" to the "Y2K Bug."

The two volumes should serve practitioners, scholars, and students as a reference, sourcebook, and gateway into the constellation of resources, theories, and practices that make up contemporary crisis management. It should additionally serve to inform journalists about the material conditions and theoretical assumptions that underpin crises, so that as events unfold, the media may more accurately inform and usefully guide the public.

Crisis managers face a paradox—in the words of Swiss playwright Friedrich Dürrenmatt, "The more human beings proceed by plan, the more effectively they may be hit by accident." To some degree, this paradox may be generic to the human condition because anytime people seek to secure their own well-being through mastery of the environment, their intentions may be frustrated by fate and the limits of their knowledge, and because this frustration has emotional as well as material consequences. However, as sociologist Ulrich Beck has pointed out, the paradox has intensified within our contemporary society because "the social production of wealth is systematically accompanied by the social production of risks." In this light, as modern society has created wealth and opportunity for the citizens of the world to a greater extent than ever before, it has become increasingly fragile and susceptible to crisis.

We present this volume with the hope that it may help reduce the economic costs, environmental damages, and human suffering associated with the crises that can arise whenever unexpected events disrupt our organized world.

A

Agency Notification and Mobilization

Disasters and crises become defining events in a hazard cycle that is marked by four temporal stages: mitigation, preparedness, response, and recovery. As such, primary agencies (e.g., law enforcement, medical, armed forces, city planners, governmental, contractors) strive to "decrease vulnerability to major disaster by taking measures to reduce casualties and exposure to damage and disruption or that provide passive protection during disaster impact." In this way, mitigation strategies aim toward reducing hazard exposures and developing emergency response plans in the event of major disaster or crisis. In order for effective emergency agency response to be effective, therefore, individual social units must be well versed in different forms of proactive response that is sensitive to the community in which the emergency plan is developed. Simply put, Kathleen Tierney maintains that organizational preparedness includes developing emergency response plans; training employees to act proactively and response personnel on what to do in an emergency situation; acquiring needed equipment, supplies, and materials; and conducting drills and exercises. Further, it is imperative that members of emergency response agencies participate in "drills" that enable them to keep their rescue and recovery skills as honed as possible. In the event that a natural or technological disaster occurs, emergency plans and agencies need to be mobilized smoothly and effectively, so as to bring the greatest aid to the largest number of people within the shortest amount of time. With that said, emergency response plans are put into place to mitigate the direct effects of whatever the emergency entails by responding to the immediate needs of the disaster victims.

Because of the possibility of the occurrence of disasters of unprecedented size and destructiveness, it is necessary that each state create an emergency management agency that is charged with authorizing emergency management programs, to give the governor the power to declare a state of emergency, should the need arise, and to coordinate varying offices during a state of emergency to channel appropriate aid to the areas most in need. The state-level emergency management agency is also charged with coordinating volunteer efforts (e.g., Red Cross or humanitarian aid) and shall remain effectively the "go to" arena for entities wishing to assist in the event of disaster and after which time that a state governor has declared a state of emergency.

When emergency agencies (police, fire, emergency medical services, National Guard, armed forces, etc.) are mobilized, the primary emphasis

In order to streamline joint-rescue efforts, an ice rescue instructor from the U.S. Coast Guard Station in Cleveland Harbor, Ohio, provides instructions to Cleveland Fire Department personnel during ice-rescue training on February 3, 2010. Primary agencies strive to reduce their vulnerability to major disasters by enhancing their organizational preparedness, which includes developing emergency response plans, training employees and response personnel, and conducting drills and exercises to sharpen their rescue and recovery skills.

of their actions, according to Tierney, must be to work to "reduce casualties, damage and disruption, and to respond to the immediate needs of disaster victims." Mobilizing response agencies at the local, state, and governmental levels requires an ability to evaluate and neutralize potential threats, sending out necessary warnings to vulnerable populations regarding specific hazards in and around the disaster zone, evacuating populations requiring such, conducting search and rescue operations for victims of disasters, administering medical care, and providing emergency shelter and food until the situation is neutralized. Further, once the immediacy of the crisis has passed, emergency response agencies work to repair, rebuild, and reconstruct (if possible) damaged property, in an attempt to remove populations displaced by crisis and disaster from temporary shelters back to their permanent residences as quickly, and as efficiently as possible.

Returning to the issue of organizational effectiveness, it is clear that local, state, and federal agencies must have a plan in place that governs the way in which individual agencies will coordinate with other entities to ensure the safety of communities at risk. More specifically, it is important for emergency plans to be drawn out so that the degree of emergency/crisis is known and requisite response teams are able to jump into action when presented with specific critical issues and problems. As such, local, state, and federal governments have been charged by the Federal Emergency Management Agency (FEMA), under the U.S. Department of Homeland Security (DHS), with developing specific levels of response, including which teams will respond to specific types of threats, as well as the types of action deemed to be appropriate responses given the threat at hand.

Local, state, and federal emergency planners have identified four levels of response for emergency entities:

Level 1 indicates routine operations. Occurring and forecasted events present little, if any, threat. Events are monitored and managed successfully by the appropriate agency, but additional emergency agencies are not required to respond.

Level 2 indicates a "heightened sense of awareness." Occurring or forecasted events include a potential or present threat, for example, weather or river watch/warning, volcano status changes, multiple wildfires, extended search and rescue, or a law enforcement action. "Events exceed routine, but responsible offices are able to manage with additional support from commonly used sources," according to the definition of the Alaska Division of Homeland Security and Emergency Management. At this level, the Department of Homeland Security and emergency managers may develop search and rescue teams, and may also call upon local emergency planners to "mobilize additional staff, as well as to continue to evaluate" the critical issues at play during the incident. It is important to note, here, that at this level, local, state, and federal emergency managers, acting under the rubric of the Department of Homeland Security, maintain the primary responsibility for managing the integrity of the disaster zone, together with the management with the situation.

Level 3 indicates that an "actual event has occurred or may be imminent," for example: river flooding disrupts public transportation, extended search and rescue requires interagency support, a wild land fire requires evacuation and shelter planning, or a raised Homeland Security threat level. At this level, a local emergency operations center is opened, and elected leadership (state governors, the president of the United States, etc.) may declare a disaster area, so as to release federal funds (administered through FEMA) to assist with the immediacy of displacement following a major emergency. When mobilized at this level, local, state, and federal agencies work together to manage the local crisis. At the mobilization of a Level 3 crisis, the Department of Homeland Security maintains the primary jurisdiction over the crisis but may seek support from other agencies to assist with crisis recovery.

Level 4 is invoked in response to the most extreme life-threatening and/or property-damaging event. Examples include a river flood, sea storm surge, or tsunami that displaces residents and damages structures; or a woodland fire that requires evacuation and sheltering of residents; or occurrence of a damaging earthquake. At this level, the situation is so dire that it cannot be handled exclusively at the local level. Instead, Level 4 crises require significant mobilization of emergency resources from multiple levels of government. During these sorts of extreme emergency events, significant interagency cooperation is a must, and it is achieved through a statewide disaster declaration by the governor. Once again, at this level, primary crisis response is developed, coordinated, and mitigated by the Department of Homeland Security and FEMA. However, in the event that the crisis at hand exceeds what the state and local governments can provide, the governor of the affected state(s) may file a request for a Presidential Disaster Declaration. In so doing, and if the president does declare a specific area as a disaster zone, this action mobilizes federal aid resources and funds to be administered by FEMA.

At the local and state levels, therefore, specific criteria are referenced in such a way as to determine the level of preparedness and potential for crisis in a given region. This analysis includes, but is not limited to, the following issues affecting entities that may find themselves in a disaster zone:

- Actual or forecasted weather events that may cause significant impacts on citizens and their property.
- "Occurring or predicted geologic events that can cause impacts to people, property and transportation systems [Normally these will be volcanic eruptions or increases in seismicity. Earthquakes could change preparedness levels, however that will normally occur after the event]" (state of Alaska definition).
- Wildfire activity throughout the state that impacts other agencies.

- Availability of emergency response and recovery resources in the state.
- Major events occurring in communities that may impact their response capabilities (such as power failures, water and sewer system disruptions, fires).

In sum, agency notification and mobilization remain linked to the type of crisis being experienced, the breadth of resources needed to combat the crisis, and how widespread and far-reaching the critical issues are, vis-à-vis the types of resources available to combat them on a local, state, and/or federal level. Further, one additional component must be considered when evaluating issues of agency notification and mobilization, namely, the role of social media (Facebook, Twitter, Foursquare, Google Plus, etc.) not only in creating fast and easy access to victim/missing persons lists but also in serving as a central point through which volunteer agencies and groups can mobilize their resources and network with others in a quick and easy-to-use platform. Further, social media work to bring communities together quickly and enable an important volunteer platform for the mobilization of resources in addition to those resources that are brought in by local, state, and federal governments. This is especially important when conventional forms of communication break down, as was the case with the two-way radios during the 9/11 terrorist attacks, and during Hurricane Katrina, when volunteers formed the Cajun Army—a group of volunteer boat owners who organized themselves and then braved the waters in the Lower Ninth Ward of New Orleans to rescue people from their rooftops and from the toxic flood waters. As such, while the conventional forms of networking and drawing upon local, state, and federal resources are important, indeed, these efforts are often augmented by the mobilization of the masses, who, if they have resources available to them, often jump into the fray to assist conventional aid workers, often with extremely positive results.

Issues relating to agency notification and mobilization are complex, as communication among and between local, state, and federal agencies can often be mired in red tape. However, recognizing that significant changes have been made since the well-documented debacle immediately following Hurricane Katrina involving the breakdown in getting aid to those who were trapped in the Lower Ninth Ward of New Orleans and in the shelters of last resort (the Superdome and Convention Center), social media sources (Facebook and Twitter) have also taken hold as key social institutions available to mobilize resources in the event of significant disaster or crisis. As the crisis emanating from Hurricane Katrina has made exceptionally clear, not only do local, state, and federal entities play a role in the mobilization of resources (and only do so when notified by official state personnel), but social media also play a pivotal role in bringing aid to victims of crisis and disaster.

Air Traffic Control

Because a crisis is considered to be an unexpected event of catastrophic proportions, air traffic control would seem to be an occupation with an extremely high potential for such occurrences. It is true that the potential exists. However, almost every action an air traffic controller takes works toward preventing the development of a crisis situation. In the event of a crisis that exceeds the mental or physical ability of the controller to actually control, such as a catastrophic mechanical failure of an aircraft, it is the controllers' job to protect the remaining aircraft under their control from becoming involved. Because of the nature of the work, air traffic controllers must remain completely focused on their traffic picture. Controllers cannot be distracted simply because the likelihood or potential for an emergency aircraft exists. When it does happen, the controllers must exercise their training, judgment, and experience to manage the situation to the best of their ability.

Training to Prepare

Regardless of the profession, the most effective way to prepare for the management of a crisis is training. To be most effective, the training should be of the highest possible fidelity. The military forces call it "training as you fight." The conditions should be as realistic as possible. This is important in order to elicit the same level of emotions and response that an individual would experience under real-time emergency or crisis conditions. This provides an individual with the optimum conditions to develop the skills required to make the decisions and to take the actions to head off or to mitigate the effects of such an event.

Air traffic controllers begin early with the training process. The vast majority of controllers are graduates of Air Traffic–Collegiate Training Initiative (AT–CTI) schools. These are colleges and universities selected by the Federal Aviation Administration (FAA) to provide training to undergraduate students attending these institutions. The training includes classroom lectures, laboratory simulations, and assessments of their performance.

Upon graduation, the students are hired by the FAA and attend the Air Traffic Control Academy in Oklahoma City, Oklahoma. There the new employees receive additional training by the FAA to prepare them for the type of air traffic control facility to which they will be assigned.

Once they graduate from the academy, the controllers arrive at their facility of assignment and begin the most extensive portion of their training. The actual facility training can take up to several years, depending on the complexity and air traffic volume of the facility. Of course, the busier facilities require a much longer training period before the controller is fully certified to work traffic on his/her own without the assistance of a trainer.

During their training time the controllers are exposed to as many types of emergencies as possible through the use of simulation. This helps in the development of a fine-tuned response that is mostly human reflex. Early response to a crisis often means attempting to make decisions about how to handle the situation while under stress and while lacking key—and often vital—pieces of information. The first thing controllers are trained to do is to acquire enough information to enable the controller to provide the required air traffic control services. Next, the controller complies with the desires of the pilot and assists with the emergency to the maximum extent possible while keeping all other air traffic clear of the situation.

The Crisis

There are certain characteristics that can be associated with any crisis. First, there must be a threat of catastrophic proportions. Second is the element of surprise. Third is a short decision time in which to attempt implementation of a management effort. If one were to question any air traffic controller for an example of such a situation that met all the criteria, without a doubt the unanimous response would be September 11, 2001.

Even though they were not aware of it at the time, air traffic controllers were the first ones to know there was a potential problem developing. Shortly after American Airlines Flight 11 departed Boston, the Air Route Traffic Control Center (ARTCC) watched the aircraft as it proceeded off its route. The aircraft had gone "radio silent" and stopped obeying instructions. Next, the transponder went off. (The transponder provides controllers with vital information, such as the aircraft's altitude and ground speed.) Although this is unusual, this same kind of situation could be expected if an aircraft were experiencing some type of an emergency and attempting to return to the departure airport. Controllers continued to attempt to reestablish communications with the plane and did what their training and experience told them to do—get other traffic out of the way.

When the second, third, and finally the fourth aircraft began to ignore instructions, the entire picture changed. This was not just unusual, this was impossible. By this time, everyone knew that a crisis was unfolding and efforts to manage it had already begun. The military had been alerted and had scrambled fighter jets to intercept the hijacked flights from a base over 150 flying miles from New York.

Managing the Crisis

As the terrorists used the hijacked aircraft to inflict maximum physiological and psychological impact on the American public, the FAA gave a command that had not been heard in the history of air traffic control: Everyone lands, no one takes off.

At the time the FAA made the decision to clear the skies, there were nearly 4,000 planes in the air over the United States. The air traffic controllers responded to the crisis armed with their ability and experience. They buckled down and did their jobs just as they had been trained to do. However, this time the job was of a magnitude never before experienced. Hundreds of thousands of people found themselves in destinations totally unfamiliar to them. Small airports were stretched to their limits as they faced the challenge of attempting to park the grounded flights as they arrived in what seemed to be never-ceasing numbers. And then it was done. Remarkably, the nation's air traffic controllers had landed every plane in the nation's airspace in less than three hours, without a single accident. A crisis management plan had, for the most part, been developed and implemented on the spur of the moment and had been historically successful.

These air traffic controllers did not arrive at their assigned facilities on the morning of September 11 with a crisis management plan on their minds or even considering that a crisis might occur. That is the way it is every day. Controllers sit down and do the job with the assurance that if an emergency or crisis arises, they possess the skills, ability, judgment, and training to manage the situation within the limits of their control.

Air Travel

Crises in air travel have occurred since humans took to the air. Safety concerns related to unstable weather conditions, structural safety of planes, and inadequate pilot training were associated with early air crashes. With the exception of a few notable accidents, air travel is the safest mode of mass transportation available. However, current threats associated with air travel are most likely a result of terrorism, environmental events, or communicable disease.

Terrorism and Air Travel

Commercial aircraft safety came to a crisis on September 11, 2001, when four commercial aircraft were commandeered in flight. One was deliberately crashed into the Pentagon, the center of U.S. military operations in Arlington, Virginia. Two other airplanes were crashed into the Twin Towers of the World Trade Center in New York City. A fourth airliner failed to accomplish its mission—believed to be a deliberate crash into a high-profile target in Washington, D.C.; instead, the plane was crashed into a field in a rural village in western Pennsylvania. Cell phone communications between passengers and family members during the flight revealed that some of the passengers attempted to wrest control of the plane away from the hijackers and their efforts may have averted a fourth successful terrorist attack on a U.S. population center. None of the passengers or terrorists survived the crash. The four airliners were not hijacked (taken over) for the purpose of demanding money, release of political prisoners, or demands to be flown to safe havens outside the United States. Instead, the takeover of the airplanes was done with the intention of using them and their jet fuel loads as deadly terrorist weapons.

In the aftermath of the 2001 attacks, airline passengers have recognized the risk of losing their lives in suicide bomber attacks. Passengers have responded with increased vigilance and readiness to actively take down terrorists and disturbed individuals who threaten aircraft and passenger safety.

Travelers aboard a December 22, 2001, flight from Paris to Miami reported the smell of smoke, and a struggle ensued between the cabin crew and a male passenger who was later identified as a terrorist. Passengers quickly came to the aid of the cabin crew and restrained the individual with improvised handcuffs and the administration of a sedative. The plane was diverted by U.S. authorities and safely landed.

In a separate incident, on December 25, 2009, a male terrorist aboard a flight to Detroit, Michigan, from Amsterdam, the Netherlands, was observed trying to detonate an explosive device in his underwear. Passengers rapidly responded on hearing firecracker-like sounds, smelling smoke, and seeing flashing lights. The passengers and crew members restrained the would-be bomber, and the aircraft arrived safely without injury or loss of life.

Airline passengers aboard a January 6, 2011, flight from Oslo, Norway, to Istanbul, Turkey, thwarted a hijacking attempt by wrestling the would-be hijacker to the floor of the plane. One passenger secured the use of a fire extinguisher and fired it like a gun, aiming it at the hijacker's face. No serious injuries occurred, and the crew and passengers were safely landed.

With the urging and assistance of flight crew members, passengers forcibly restrained the captain of a March 27, 2012, JetBlue flight between New York City and Las Vegas, Nevada, who displayed severely disturbed behavior by racing up and down the aisle of the plane. The plane landed in Amarillo, Texas, where the disturbed captain was taken into custody. No injuries were reported.

The accounts of passengers taking successful life-saving actions to protect themselves in flight are examples of heightened awareness and behaviors learned from the tragedy of the 2001 terrorist attacks and the subsequent successful outcomes of passenger takedowns of terrorists reported in the media. Moreover, airborne collaborations between flight crews and passengers have resulted in swift actions against terrorists.

Environmental Crises and Air Travel

Sustained volcanic activity in Iceland spewed ash into the atmosphere during May 2010. Decisions on halting flight activities in ash-impacted areas were made by European governments, and 1,000 flights were canceled. The International Air Transport Association (IATA), an aviation industry group, called for action to improve decision making on when and where grounding of planes should be made in the event of future volcanic eruptions; the agency called for improved research to evaluate flight safety conditions in ash-laden atmospheres and reported that the European states had failed to take swift action in the face of the volcanic ash crisis. The IATA called for common policies, such as existing policies for flying in hazardous weather conditions, to be applied to determine safe flight routes when confronted with volcanic ash threats. Unlike in Europe, in the United States the Federal Aviation Administration (FAA) provides detailed information on ash levels and no-fly zones that is made available to the aviation industry.

Communicable Disease Threats to Air Travel

Communicable diseases such as influenzas—including H1N1 (referred to as avian or bird flu), H1N1/09 (commonly called swine flu), and severe acute respiratory syndrome (SARS)—are examples of highly contagious viruses that can be transmitted from animal to animal or from one person to another. Other forms of communicable diseases include cholera, tuberculosis (TB), smallpox, plague, yellow fever, diphtheria, and viral hemorrhagic fever. Public health agencies such as the Centers for Disease Control and Prevention (CDC) in the United States and the internationally based World Health Organization (WHO) are authorized to identify individuals who pose communicable disease threats to the public. In the United States, the CDC, under the auspices of the federal Department of Health and Human Services, may prohibit individuals suspected of having a communicable disease from entering the country. Isolation and, infrequently, quarantine measures may be taken to protect the public from exposure. The confined space and limited air transfer in the pressurized atmospheres of airplane cabins increases the danger of spreading communicable diseases in close quarters, not only to the passengers and crew, but also to the unsuspecting public when communicable disease carriers arrive at their destinations, blend into the general population, and become difficult to track by public health agencies. The International Cooperative Arrangement (ICAO) for the Prevention of Spread of Communicable Disease through Air Travel (CAPSCA) is an international agreement between governments, public health agencies, and the aviation industry to combat the transboundary spread of communicable diseases through air travel and air cargo transport. CAPSCA serves as a communication vehicle for nations to more effectively work together to address communicable disease crises involving air travel. A critical function of CAPSCA is to help countries adhere to WHO International Health Regulations governing communicable disease transmission.

All-Hazards

A hazard is a dynamic phenomenon that threatens people and their possessions, assets, and activities with injury, damage, destruction, or curtailment. Broadly, there are four kinds of hazards: natural (e.g., floods, earthquakes), technological (e.g., transportation crashes, toxic spills), social (e.g., riots, crowd crushes), and intentional (e.g., acts of terrorism, hostage taking). The simplest manifestations of hazards are those that involve a single agent (for example, an earthquake) acting upon a simple situation of vulnerability (for instance, houses that may be damaged). However, it is increasingly recognized that hazards can strike in complex ways. For example, a "natech" hazard is a combination of a natural and a technological agent. One of the largest events of this kind was the Tohoku earthquake and tsunami of March 11, 2011, in eastern Japan that led to a major radioactive release from the Fukushima nuclear power plant.

The intersection between hazards can take different forms. A reservoir dam, for example, may be subject to the following risks: flooding (inadequate spillway design), seismic activity (structural damage, dislevelment because of tectonic uplift or subsidence), sudden landslides or avalanches that cause water waves, sedimentation that reduces reservoir capacity, or merely structural failure. This, then, is a multihazard situation in which naturally generated extreme events interact with the dam, an anthropogenic construction. An alternative scenario is one in which there are cascades of hazard impacts. In one instance, an earthquake damaged a factory that contained a tank full of sulfuric acid: the tank ruptured and spilled its contents into the local river. The first consequence was the structural damage, the second was the need for a toxic spill cleanup operation, and the third was an alarm about possible corrosion of bridge abutments and acidification of groundwater supplies.

Complex and Cascading Hazards

In complex and cascading hazard situations, the principal or triggering event is not necessarily the dominant one in terms of the gravity of consequences. For instance, damage to buildings and structures may result directly from dynamic acceleration of the ground during an earthquake. However, in areas where lenses and strata of saturated sand are common surficial geological formation, liquefaction damage may be more serious. Moreover, major earthquakes commonly cause thousands of landslides. In areas with urbanized, unstable slopes, landslide damage may be more serious than the direct results of the shaking. This was the case in the 1976 Guatemala City earthquake, which severely damaged housing on canyon sides that were heavily affected by seismic landslide activity.

All-Hazards Zonation

The concept of the "hazardousness of place" has been vigorously promoted since the 1960s. At that time it was already common to compile detailed maps of single hazards and their probable effects (for example, landslide susceptibility maps). By the 1990s, advances in spatial depiction had greatly facilitated the ability to combine geographical representations of hazards in order to show how different locations are generally at risk. In particular, the overlay facility of a geographic information system (GIS) enables hazard maps to be compared in order to calculate the hazardousness of place.

Microzonation can be defined as the identification of separate areas that have different potentials for specific hazard effects. Because the zones need to be distinguished from one another, they are usually separated by thresholds, for example, in the force of the mapped phenomenon in relation to its ability to cause damage. Microzonation mapping and analysis needs to be conducted at a scale that can be applied to individual buildings or short stretches of road, or at least small groups of structures, so that remedial and protection work can be carried out on the basis of the hazard information.

The simplest form of microzonation is the single-hazard, single-purpose kind. For example,

A Center for Domestic Preparedness (CDP) team carries a simulated victim through the decontamination process during an exercise at their headquarters in Anniston, Alabama, on August 4, 2011. Responding to all-hazards, mass-casualty events is a core principle of CDP training. In the 1990s, the U.S. Federal Emergency Management Agency developed the "all-hazards" emergency plan, a set of operating procedures and directions for action that could be adapted to a wide variety of different threats.

snow avalanche hazard can be mapped in detail for the purposes of determining potential loss of life or damage to buildings. However, many places are threatened by more than one hazard, or they can be subject to complex or cascading hazards. This very significantly complicates microzonation but greatly increases its explanatory power. Moreover, there are different reasons for conducting microzonation surveys, and therefore the fullest development of the technique involves multiple hazards (and hazard interactions) for multiple purposes. This is the approach that most closely depicts the "hazardousness of place." One limitation stems from the range and quality of data: Even a fully microzoned area can depict only known hazards, and specifically, those whose magnitude and frequency can be measured in spatial terms. This may require long periods of observation. Nonetheless, combining microzonation maps with scenarios of hazard impacts can provide a firm basis for planning risk reduction and emergency response measures.

Case Studies in the Lack of All-Hazards Planning

In the past, emergency plans have been written in order to define procedures for responding to single hazards. This has had an unfortunate consequence: if the area in question suffers from a different form of impact, the plan must either be spontaneously adapted to the situation as it evolves or be abandoned. For instance, on September 11, 2001, the District of Columbia had to cope with the effects of the terrorist attack on the Pentagon and ensuing disruption as people tried to leave the city en masse, using a plan that had been developed for managing the possible effects of the so-called millennium bug, the hypothesized malfunction of computer systems on January 1, 2000. This resulted in management that was less than optimal.

In another example, for many years the city of Florence, Italy, had an emergency plan that was written in response to urban flood hazard, because the largest and most devastating disaster that the city ever had cope with in modern times was the flood of November 3–4, 1966. Although relatively minor flooding did occur in the 1990s and 2000s in Florence, the city had to cope with a terrorist bomb attack in 2003, a fatal crash at the local airport in 1998, and major snow disruption in 2010. In none of these cases could a plan to deal with flooding be regarded as an adequate source of direction.

All-Hazards Planning

In the 1990s the U.S. Federal Emergency Management Agency (FEMA) developed the concept of the modern "all-hazards" emergency plan. This could include chapters on specific hazards, normally those of greatest importance in the area covered by the plan, but its core would be a set of standard operating procedures and directions for action that could be adapted to a wide variety of different threats, including those that manifest themselves in complex or cascading ways.

Hazards that are frequent or of high magnitude and that are known to affect a particular area at recurrence intervals of less than half a century should receive specific treatment in an emergency plan. The level of detail with which the plan treats them will be a function of the precision and depth with which they are assessed. The response to those hazards that are unexpected and cannot be predicted or adequately assessed should be governed by standard, generic procedures. Hence the all-hazards plan needs to be adaptable to a range of threats, from those that are very well known and on which there is a considerable amount of information to those that are highly unusual or improbable—but not impossible.

In the United States, FEMA encourages planners to use an all-hazards framework. National management structures are specifically designed to accommodate this. The National Incident Management System (NIMS) provides a means of implementing on-site incident command for all kinds of hazard, crisis, and response. The National Response Framework (NRF) specifies flexible, scalable, and adaptable response structures for managing national emergencies. The underlying aim is to manage emergencies effectively and efficiently, whatever their cause and consequences. Finally, organizations such as the Citizen Corps Council (CCC) have an all-hazards role in providing nongovernmental local response to different threats in conjunction with governmental authorities at various levels. This whole setup is beset by significant obstacles in that some laws, norms, and regulations are not compatible between federal, state, and local levels. Moreover, there are "gray areas" in which it remains to be determined which level of government should take responsibility for certain actions, such as search and rescue. This further complicates a situation that already has many intricacies.

Multidimensional Emergency Management

One of the biggest challenges of modern emergency management is to be able to make effective decisions in environments characterized not merely by large amounts of data but also by a huge breadth of types of information. In advocating advanced knowledge management techniques, Dag Von Lubitz et al. noted the following: "In the ultra complex setting of mega-disasters, decision-makers must process vast amounts of multidisciplinary, often poorly organized, disparate data and information and convert it into relevant and usable knowledge."

The multilayered response to cascading or complex hazard events may require response from as many as 35 different professions and disciplines. Hence, a further challenge is to provide a common language and culture capable of integrating disciplinary perspectives and promoting interoperability. Half the problem of responding to a crisis is not a question of knowing how to do one's own job but one of appreciating and understanding the actions of other responders, especially those in fields different from one's own.

A further challenge is to be able to extrapolate events and to anticipate unusual consequences in order to be prepared to manage them well. In order to do this, the interaction between hazards needs to be studied attentively, as do the ramifications of societal impact. Areas of the latter that are commonly neglected in emergency planning include the care of inmates in prisons during threatening disasters, veterinary emergency response, and cultural heritage planning. Regarding the last of these, the fragility and irreplaceability of many cultural artifacts makes it imperative to adopt an all-hazards approach to planning. One cannot allow the heritage to be fully protected against one hazard but then destroyed by another that was not foreseen. Once again, detailed procedures can be worked out for common and anticipated hazards, while generic ones must be used for unpredictable events.

In synthesis, it has become generally accepted practice to adopt the all-hazards approach when planning for and managing emergency responses. This must involve tackling the full range of known hazards, using scenario modeling to constrain uncertainties to manageable levels. It must involve designing generic procedures to cope with hazards that are too rare or improbable to be foreseen and on which no data from past impacts exist. Finally, it requires careful attention to the interaction between hazards, including cascades of effects, as the consequences of one impact trigger other hazards and other effects. The complexity of such situations requires emergency planners and managers to use modern tools, such as GIS and knowledge management systems.

Alternate Site, Corporate

An alternate site refers to a physical location that employees may work from in the event that their primary workplace is damaged or destroyed.

Needs of Different Corporate Groups

Alternate sites need to be considered for specific groups in the corporate environment. One is an identified alternate site for a crisis management team to convene, such as a backup emergency operations center (EOC) or command center. A second is an identified site for specific business units for emergency relocation. Another is a backup site for a company's data center.

A backup EOC or command center should be situated away from the primary location. Considerations for a location should include environmental concerns (i.e., population density, urbanization) and local hazards (flood zones, fault lines, etc.). It should be in an area not likely to be impacted when the primary location might be impacted. Distance should be a consideration but may vary based on need.

Each business unit within a company should have a strategy for where its work can be continued in the event that its office space is inaccessible. In large companies, other company-owned facilities should be considered. Additional office space in proximity to the affected site may be able to host essential employees and assist in continuing essential processes and operations.

In the absence of other company facilities in close proximity, alternate worksites can be arranged through private vendors. Hotels and vacant buildings may be utilized to accommodate personnel and necessary office equipment. Portable structures, such as trailers, should be considered as well. A frequent concern with this approach is vendors overcommitting. If contracting such services, note in the agreement whether the vendor is allowed to contract with more than one company for a given site or facility. The intentions of the vendor are reasonable, as it is not likely that all businesses using their services will need to do so at the same time. Having many clients means they can offer the protection at a more affordable rate. However, in a large-scale incident that affects many businesses, it is likely that these services will be overcommitted.

Alternate sites may also be secured in the form of reciprocal agreements or memorandums of understanding (MOUs) for the utilization of space for the needed connected infrastructure and employee accommodations should the need arise.

Mobile work solutions are strategies that could be used in the event that a physical workplace is unavailable. Telecommuting can allow employees to work from home when given the appropriate technology in advance to do so. Some employees will be able to continue essential work flows if given access to e-mail, software programs, and company networks from their home computers.

A backup site should be considered when a company's business is dependent on a sophisticated technology infrastructure. This focuses on information technology (IT) and other machinery-related systems that drive a company. If possible, alternate sites should be built to offer 24/7 backup protection and automatic migration of data when the primary system becomes disrupted.

Types of Alternate Sites

There are three types of alternate sites: a cold site, a warm site, or a hot site. The differences between the types are determined by the costs and efforts required to implement each.

A cold site is an identified space that does not contain any resources or equipment needed for business operations. Equipment and resources must be installed in such a location after the disruption has occurred and needs have been identified. This requires the most time to set up during a crisis and is common with general business functions. This is traditionally viewed as the most cost-efficient approach. However, the cost of purchasing equipment during a crisis and on short notice may be higher than in normal times. It may also be more difficult to obtain—and in some cases impossible to obtain—under emergency conditions.

A warm site is an identified space that contains partial resources or equipment needed for business operations, such as desks, chairs, telephones, and computers. This requires less time to set up during a crisis than a cold site and may also be useful for many of the general business functions.

A hot site is an identified space that has the resources and equipment to allow for a complete continuation of a business function. Equipment and resources are maintained as if the site was the primary location. Hot sites vary in size and capability based on the need of the business. This requires minimal time to set up and can be justified when downtime of the business function is detrimental to the overall business. This is seen with specialized business functions. A big and often-overlooked advantage of a hot site is its ability to be used every day for training purposes or as extra work space.

Business Continuity Planning

The identification of an alternate site is part of the business continuity planning process and should be done early in the development of the emergency plan. The alternate site should provide for the continuing of key business functions as identified in the Business Impact Analysis (BIA). For the most part, each business unit within a company should be responsible for identifying its own alternate site strategy versus the company as a whole. This way the individual needs and concerns of each business unit will be addressed appropriately in the business continuity plan.

American Society for Industrial Security (ASIS) SPC.1-2009

The ASIS International SPC.1-2009 standard, Organizational Resilience: Security, Preparedness, and Continuity Management Systems—Requirements With Guidance for Use, has been adopted by the U.S. Department of Homeland Security (DHS) Private Sector Preparedness (PS-Prep) program. The PS-Prep program is designed to improve the preparedness of organizations through conformance to established preparedness standards and best practices. ASIS International SPC.1-2009 provides a cost-effective approach to managing risks of disruption by providing a balanced framework for the minimization of both the likelihood and consequences of disruptive events.

ASIS International

The American Society for Industrial Security (ASIS) was founded in 1955 and officially changed its name to ASIS International in 2002. ASIS International is a professional security nonprofit organization with over 37,000 members and 200 local chapters worldwide. ASIS represents the interests of the security management profession in such areas as business, media, government, and public entities. Additionally, ASIS offers professional security educational materials and programs, certifications, workshops, and conferences. Approximately 20,000 security professionals from around the world attend the ASIS Annual Seminar and Exhibits conference.

In the public, private, and nonprofit sectors, security management responsibilities often include risk management, crisis management, business continuity, and preventing or mitigating other organizational threats. In support of these high-level responsibilities, ASIS developed the organizational resilience ASIS SPC.1 American National Standard, which is one of three standards adopted by the PS-Prep program, as discussed below.

Private Sector Preparedness (PS-Prep)

In 2007, the U.S. Congress directed the DHS to establish and implement the voluntary private sector preparedness accreditation and certification program. As a result of this directive, the PS-Prep program is designed to improve the preparedness of organizations through conformance to established preparedness standards and best practices.

PS-Prep enables organizations to implement the necessary steps for instituting and maintaining a comprehensive management system addressing business continuity, organizational resilience, and emergency and disaster management. Additionally, DHS provides recognition for those entities that certify to the adopted preparedness standards.

PS-Prep is a voluntary program, primarily serving as a resource for private and nonprofit entities interested in instituting a comprehensive business continuity management system. Incorporating three industry standards, PS-Prep offers organizations the opportunity to develop and maintain certification to U.S. nationally recognized approaches to resilience and preparedness. A core function of ASIS International is to promote organizational preparedness. ASIS International, in line with PS-Prep program objectives, developed the ASIS International ASIS SPC.1-2009.

The three DHS-adopted PS-Prep standards are (1) ASIS International's Organizational Resilience: Security, Preparedness, and Continuity Management Systems—Requirements With Guidance for Use (also known as ASIS SPC.1—American National Standard and ASIS International SPC.1-2009); (2) the British Standards Institution's BS 25999 (Part 1 and 2); and (3) the National Fire Protection Association's NFPA 1600, Standard on Disaster/Emergency Management and Business Continuity Programs.

ASIS International SPC.1-2009

The ASIS International SPC.1-2009, also known as the ASIS Organizational Resilience Standard, helps an organization design a system to reduce the likelihood and minimize the consequences of disruptive events. The standard provides a framework for organizations to assess the risks of disruptive events (emergencies, crises, disasters); to develop a proactive strategy for prevention, response, and recovery; to establish performance criteria; and to evaluate opportunities for improvement. The standard guides entities to implement an organizational resilience management system based on specific organizational and stakeholder needs. SPC.1-2009 can be used by organizations to facilitate resilience and preparedness as well as to seek certification recognized by PS-Prep. The standard can be integrated with quality, safety, environmental, informational security, risk, and other management systems within an organization. SPC.1-2009 is designed to be flexible and scalable, to adapt to an ever-changing environment.

The standard is applicable to all sizes and types of organizations (private, nonprofit, public, domestic, multinational, etc.), creating a balanced strategy for both likelihood and consequence reduction for incident prevention and management based on the process approach, which emphasizes the importance of the following:

- Understanding the organization's risk, security, preparedness, response, continuity, and recovery requirements
- Establishing a policy and objectives to manage risk
- Implementing and operating controls for managing organization's risk in the context of the organization's mission
- Monitoring and reviewing the performance and effectiveness of the organizational resilience management system
- Continual improvement based on objective measurement

SPC.1-2009 adopts the plan-do-check-act (PDCA) model, which is applied to structure the organizational resilience management system processes as identified in the following:

- *Plan*: Establishes management system policy (includes a policy statement demonstrating management commitment), objectives, processes, and procedures relevant to managing risk and improving security, incident preparedness, response, continuity, and recovery to deliver results in accordance with an organization's overall policies and objectives based on risk assessment and impact analysis.
- *Do*: Addresses implementation and operation of the management system policy, controls, process, and procedures.
- *Check*: Assesses and measures process performance against management system

  policy, objectives, and practical experience and reports results to management for review.
- *Act*: Take corrective and preventive actions, based on the results of the internal management system audit and review, to achieve continual improvement of the management system.

SPC.1-2009 is approved by the American National Standards Institute (ANSI) and based on the International Organization for Standardization (ISO) management system standard model. The standard integrates plans for managing the risks of disruptive events into their enterprise-wide risk management programs, consistent with the ISO 31000, Risk Management, Principles, and Guidelines. Further, SPC.1-2009 leverages existing investment in other ISO management systems to include the following, in order to improve security, preparedness, and continuity performance:

- ISO 9001, Quality Management Systems
- ISO 14001, Environmental Management Systems
- ISO 27001, Information Security Management Systems
- ISO 28000, Specification for Security Management Systems for the Supply Chain

Conclusion

The standard provides a comprehensive management system approach including security, preparedness, response, mitigation, business/operational continuity, and recovery for disruptive incidents facilitating organizational resilience.

Arms Control

In the post–World War II era (1947–87), arms control was largely a function of superpower rivalry between the United States and the Soviet Union as the respective nuclear arsenals, delivery vehicles, advanced missiles, bombers, and nuclear attack submarines made nuclear war and mutual assured destruction a real possibility. Until efforts were made by the two nations to reduce their nuclear capabilities, there had been very limited efforts in the United Nations framework for arms reductions among those advanced states with a fairly robust military. The UN Conference on Disarmament was designed to deal with arms control issues affecting developed nations in areas as diverse as land mines, outer space, fissile material, and the development of advanced weaponry.

Arms control generally came to be understood in terms of its primary principles, which included (1) verifiable and parallel reductions in strategic arms, (2) measures to build confidence between states over further arms developments and research, (3) net reductions in certain weapons systems deemed to be "destabilizing" to a region of the world, and (4) commitment to a verifiable treaty that obliges the parties to engage in balanced reductions of nonstrategic systems over a period of time, which often includes provisions for on-site inspection and external review and verification of these reductions. Against this backdrop was the ambiguous yet firm right each sovereign nation retained under the United Nations (UN) charter to defend itself against attack while simultaneously pledging itself to efforts that promote global security while reducing the distribution and growth of global arms.

History of Arms Control

Historically, one of the first such efforts was the 1899 Hague Convention, which tried but failed to limit armaments to a great degree, while other subsequent Hague conferences addressed issues of arbitration and principles and treaties of warfare. For instance, early Hague conventions approved prohibitions on the use of asphyxiating gases and the use of expanding bullets (dumdums) and discharges of projectiles or explosives from balloons. However, reflecting a perennial problem with such treaties where compliance is seldom achieved, none of these agreements was observed during World War I. One significant effort following World War I from 1921 to 1922 was the Washington Conference, which aimed to reach disarmament, arms limitation, and arms control agreements designed to halt the global naval arms race. In 1930, the London Naval Conference tried to formalize earlier agreements; however, Italy and France refused to agree to an extension of the treaty and Japan withdrew in 1935. The 1925 Geneva Protocol, which now has some 130 parties, prohibited the use of asphyxiating and poisonous gases and bacteriological weapons in international conflicts, though it did not apply to internal or civil wars. Ironically, many countries retained the right to use such weapons in a retaliatory strike, and some attempted to limit first-strike prohibitions altogether.

By comparison, the major arms control treaties that obligated the United States and the Soviet Union to balanced nuclear reductions included the following:

- START I (1991): The United States, Russia, and the former Soviet republics agree to limit major nuclear weaponry. The agreement became effective in 1994, to be implemented by December 2001. The major limitations include the following:
    - » 1,600 deployed intercontinental ballistic missiles (ICBMs), submarine-launched ballistic missiles (SLBMs), and heavy bombers for each side
    - » 6,000 warheads, of which no more than 4,900 may be on ICBMs and SLBMs
- START II (1993): The United States, Russia, and the former Soviet republics enter into an agreement to further limit nuclear weapons. Basically, the warhead limit was reduced to 3,500, of which no more than 1,750 could be SLBMs. The U.S. Senate ratified this agreement in January 1996, but Russia has made ratification contingent on U.S. acceptance of subsequently negotiated agreements that extended the deadline and that made the Soviet republics parties to the Anti-Ballistic Missile (ABM) Treaty. Ratification was further delayed because of the U.S. intention to withdraw from the ABM Treaty. In May 2002, Russia and the United States negotiated a new treaty that, like START II, reduces nuclear arsenals by about two-thirds. This new treaty must now be ratified by Congress and the Russian Duma.

- ABM Treaty (1972): The United States and the Soviet Union agree not to develop extensive missile defense systems. The United States has maintained that testing and development of ABM systems is within the scope of this agreement. In 2002, the George W. Bush administration formally announced that the United States would be withdrawing from this treaty.

Along with these bilateral treaties there were several multilateral treaties that obligated at least 35 nations, and sometimes many more, to reductions in their respective armaments while also pledging to stem and control the further distribution and proliferation of certain weapons systems. They include the following:

- Chemical Weapons Convention (1993): A multinational agreement to eliminate production and storage of chemical weapons. Only a very few countries have not signed and ratified this agreement. There is an international inspection organization to ensure compliance. The United States has encountered some technological difficulties in destroying some of its stockpile, while Russia has faced economic obstacles in meeting destruction deadlines.
- Conventional Armed Forces in Europe Treaty (1990, modified in 1999): This treaty places legally binding national ceilings on the conventional armed forces of every country party to it and has special restrictions on forces in flank regions. It also contains conflict resolution procedures for member states. The adapted treaty will not enter into force until all 30 signing states ratify the agreement.
- Nuclear Non-Proliferation Treaty (NPT; 1968): The five nuclear weapon states (Russia, United States, United Kingdom, France, and China) agree not to transfer nuclear weapons, other nuclear explosive devices, or their technology to any non–nuclear weapon state. The non–nuclear weapon states agree not to acquire or produce nuclear weapons or nuclear explosive devices. All nations are parties to this agreement except India, Pakistan, Cuba, and Israel.
- Comprehensive Nuclear Test Ban Treaty (1996): This treaty is negotiated under the auspices of the United Nations and prohibits any nuclear explosion whether for weapons or peaceful purposes and includes a system for monitoring adherence to the ban. The treaty does not become effective unless ratified by the five acknowledged nuclear weapon states and the three threshold states of India, Pakistan, and Israel. The U.S. Senate has not ratified this treaty.

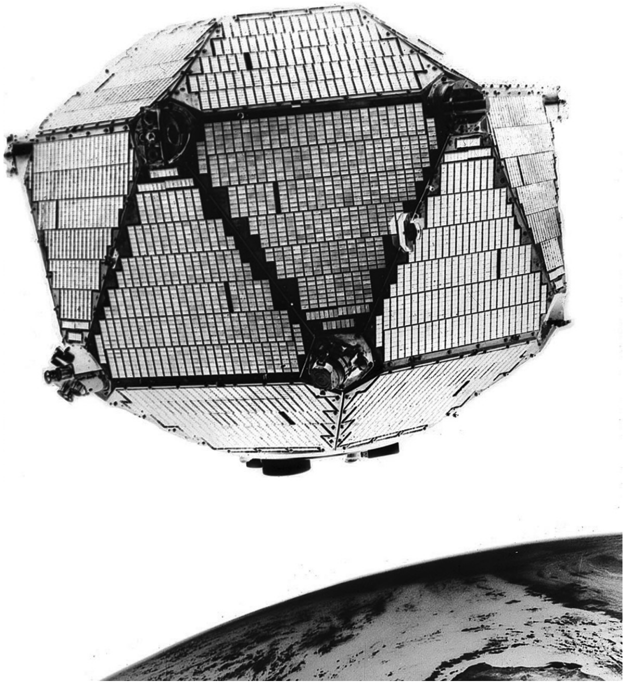
There are other treaties, such as the Land Mines Treaty, to which many states agreed, and the Biological and Toxic Weapons Convention of 1972, which is far from being complete, and yet ongoing negotiations have kept global attention on these subjects as nations wrestle with the existing and emerging array of weapons systems. There is no treaty that circumscribes international missile development, nor is there a treaty that comprehensively addresses advanced weapons systems; however, the desire for most UN nations to bring a variety of weapons systems under some form of treaty coverage and control remains very strong.

Why Arms Control?

Incentives for states to enter into such treaties are the political and presumed economic advantages of reducing arms and promoting confidence through mutual visits and efforts to contain proliferation of arms considered to be destabilizing. Another dimension to this is the irony of sovereign states pursuing weapons programs they believe simply enhance their own defensive options and strengthen their security posture. When India and Pakistan pursued nuclear weaponry, their actions took place outside the NPT and were couched in terms of the need to bolster national security. In the same vein, both North Korea and Iran have embarked on a similar course of action, relying on the ambiguous elements of the NPT to maximize peaceful nuclear research that has the innate potential for conversion to weaponization purposes.

Key issues remain as obstacles to further treaty work on global arms reductions that include the technical and operational challenges of building robust verification systems, finding equitable and enforceable definitions of "noncompliance" with treaty provisions, and agreeing on measures designed to compel states into compliance. Then there is the question of balanced and parallel reductions in existing arms systems, while weapons systems modernization and technologies continue in largely unrestricted domains. There is also the question of proliferation, arms sales, illicit arms trafficking, and the frequent practice of reverse engineering of rival weapons systems by states that used espionage to acquire weapons they need to defeat or replicate.

No easy answers exist for the steady and verifiable reductions of arms considered to be destabilizing, such as advanced fighters, attack submarines, intermediate-range ballistic missiles, and acoustic- and laser-based weapons that convey a distinct tactical or strategic advantage to their owners. The pressure to acquire an advanced weapons systems array that has genuine deterrent power and thereby discourages attacks because of the retaliatory capabilities of possessing states remains one of the most difficult challenges facing those committed sincerely to a more widespread and global move toward wider arms reductions and controls.



These Vela satellites were deployed in support of the Limited Test Ban Treaty of 1963 and carried sensors designed at Los Alamos and Sandia National Laboratories to detect nuclear explosions in the atmosphere and in space.

With advances in weapons technology and the competitive climate for strategic advantage continuing in the absence of total global disarmament, the incentive for many states to acquire robust weapons systems to increase their own security, build deterrence, and demonstrate the power of their armaments is unlikely to cease. Instead, pressures for gradual disarmament must be categorized in terms of two major areas of interest: (1) strategic systems involving nuclear forces, missiles, chemical-biological weapons, advanced laser and robotic platforms, versus (2) lesser weapons systems such as aircraft, submarines, tanks, artillery, and land mines that can be approached in different arms control venues. As a result, avenues for arms control will likely remain inside the UN system for lesser armaments within the annual Conference on Disarmament and those special and unique bilateral and multilateral treaties that address more strategic systems containing destabilizing weapons.

The right of sovereign states under the UN Charter to embark on legitimate self-defense activities is ambiguous enough to persuade any state to pursue a dynamic and strategic capability sufficient to establish a deterrent against externally based attack. This includes missile defense, robust naval and air forces, armies infused with high-technology weapons, and acquisition of strike weapons that possess strategically devastating power. However, as we know, many states have avoided this bottomless pit of progressively lethal weapons systems growth, instead relying on alliances, neutrality, or other effective nonmilitary means to protect their sovereignty.

Future of Arms Control

As new weapons systems emerge and states exhibit advantages arising from these new systems that convey deterrent power and strategic invincibility, the momentum toward further arms control efforts will likely be confined to well-known and controllable weapons systems. Some states will not have the resources or technology to stay abreast of newly developed weapons systems, while others will push ahead despite painful trade-offs elsewhere in their own economies, as North Korea did. Even states that embark on strategic missile defense systems are not immune to pressures to share this protective technology or curb development of such systems inside an arms control treaty. Missile defense, airborne lasers, acoustic wave energy weapons, and other modern systems are often seen as insurmountable national defenses creating fortress-like states that will consistently resist the opportunity to restrict or control these systems through conventional arms control measures or treaties.

Auditing

Auditing may be defined as the systematic evaluation of a system, function, task, or organization according to established and measurable standards and criteria. Accepted industry practices for business continuity have long included auditing of the areas of safety, security, and emergency preparedness for compliance with requirements both internal and external. Crisis management, as a subset of safety, security, and emergency preparedness, can reap many benefits from a rigorous and regular auditing program to establish the state of preparedness and the effectiveness of procedures, policies, programs, and processes and to provide corrective action where noncompliances or deficiencies are noted so that remedial measures may be put into place prior to failure in implementation.

Purpose of Audits

Auditing is part of preparedness. Clearly, prevention is the highest form of crisis management, and auditing to ensure that preventive measures are in place, as well as responsive measures, is a primary concern in assuring that any organization, jurisdiction, or agency is as well prepared for crisis as possible.

Audits can be performed to meet external requirements for assessment, or they can be an internal process designed to measure an agency's ability to meet its own requirements for preparedness and recovery. Sometimes both external and internal audits are mutually required, with the external audit assessing the efficacy of the internal audit as a measure of quality assurance.

Management Audits

There are several different approaches that may be adopted for the purpose of auditing plans, programs, and procedures for crisis management. Compliance audits measure the implementation of written manuals, procedures, and work instructions, and this is most certainly an effective method of measuring preparedness and response in crisis management. However, management audits make additional analyses of the agency's documents, processes, and activities to focus on results. This is a process that evaluates not just the existence of procedures, programs, and processes but also the effectiveness and suitability of these controls (in this case, to address adverse events that will result in crises that can reasonably be foreseen to occur for the agency, organization, or jurisdiction). It may include reviews and evaluation of methodology and approach. Management audits are compliance audits that additionally employ cause-and-effect analysis. Their evaluation methodology provides the opportunity to identify hazards or failures that occur in chains of events, not simply in one step of the process. For this reason, it is a more effective approach to auditing for critical processes, including crisis management.

The outcome to be considered is the ability to manage adverse events and to recover in an effective and efficient manner. The auditor(s) should ensure that careful review of processes and protocols is performed to ensure that the interrelationships can be adequately explored through the audit process.

Systems Approach

It is well established that effective management of crises is an interdependent process; many agencies, departments, and organizations work together to maximize response and recovery, and in essence, the discrete organizations become a system during crisis management. Auditing of preparedness for crises must take into account and evaluate the interactions between these critical partners. Interdepartmental and interagency communications protocols are critical elements of preparedness and should be well documented and exercised as well as included in the audit process.

Auditing Principles

The basic goals of a crisis management audit program are as follows:

- Assess compliance with all regulatory compliance and internal requirements
- Assess outcomes of programs, processes, and procedures, with emphasis on addressing known areas of difficulty or complex interactions requiring special treatment
- Ensure that all identifiable hazards are documented and addressed in an appropriate manner
- Ensure that appropriate corrective action for any areas of noncompliance or for hazards/adverse outcomes identified in the audit process are developed and implemented appropriately
- Ensure that the audit program is robust, well managed, fully implemented, and documented appropriately

An effective audit program also addresses other issues of concern to the agency, jurisdiction, or organization, including promotion of efficiency in operation, eliminating redundancies and duplication of effort, effectiveness in management and supervision, and the awareness and understanding of crisis management among all partners. Some audit findings may result in recommendations for improvement rather than corrective action for noncompliance.

Areas to be Audited

General areas of inquiry for crisis management include the following:

- Policy and plans: concept of operations, continuity of operations, continuity of government, emergency operations, crisis management, or other plans as required by statute or other requirement
- Planning process: communications, coordination, redundancy, resources, methodology (including post-incident briefing and analysis), and documentation
- Communications: protocols, procedures, unified command, public information, and documentation
- Procedures: preparedness, operations, and recovery
- Training: protocols, procedures, and documentation
- Documentation: as-built drawings, schematics, maps, etc.
- Special operations: hazardous materials, institutional operations (such as schools, hospitals and care facilities, and prisons), utilities, equipment and personnel staging, access and security, information technology, evacuations, shelter operations, weapons of mass destruction (WMDs), pandemics, and other areas as appropriate
- Reporting: statutory, internal, and external (to include after action, grant/reimbursement, etc.)

Depending on the particular threats and vulnerabilities of the organization or function to be addressed, additional areas of inquiry may be appropriate.

Audit Process

An audit cycle begins with notification to the audited department or function. Documentation pertaining to all requirements, standards, and guidelines should be requested and reviewed, and a checklist of all requirements developed. A pre-audit briefing may be held with the area to be audited to introduce the auditor(s) and the key stakeholders, to explain the audit process, to collect documentation, and to address questions and concerns of the participants.

An audit interview is held with the key stakeholders, and the checklist is reviewed to determine compliance with all standards, guidelines, and requirements. Supplemental documentation may be requested to establish compliance. Field verifications to observe preparedness activities and resources may also be appropriate.

Once compliance and noncompliance have been established though the interview and documentation review, the auditor(s) should deliver a preliminary report of these findings to the audited area. A corrective action plan is developed by the audited area to bring any noncompliances into compliance. The auditor(s) may need to provide support to assist the departments in developing the corrective action plan. In addition, any recommended improvements can be addressed in the corrective action plan as well.

Finally, the auditors may also provide assistance in the implementation phase to assist the audited area in developing documentation, implementing programs, and further assessing the corrective actions for suitability and effectiveness. When the cycle is repeated, assessment of previous areas of noncompliance will involve efficacy of corrective actions.

Audit Program

A proper audit program must be well documented and consistently administered. The components of the audit program that must be documented are the following:

- History, purpose, goals, and objectives
- Audit oversight and authority
- Audit philosophy and methodology
- Audit procedures and supporting documents (e.g., checklists, document request lists)
- Auditor qualifications and training
- Audit schedule and cycle (e.g., annual, biennial)
- Audit reporting requirements
- Review and revision cycle for audit program documentation
- Other items as required by the program objectives

There are a number of audit methodologies that may be used as models. The International Organization for Standardization (ISO) publishes a baseline quality management methodology (ISO 9001:2008) as well as an international auditing standard (19011:2011), as do a number of other national and international organizations, including the American Society for Quality, RABQSA, and private businesses specializing in crisis management. The National Fire Protection Association publishes an excellent standard for Emergency Management and Business Continuity (NFPA 1600), which includes a standardized checklist for auditing Continuity of Operations Plans and other emergency management plans, processes, and procedures. It is an excellent resource for crisis management auditing.

Auditors

In order to perform effective audits, auditors must have both training and knowledge in the field to be audited as well as in auditing itself. Training in auditing is available from the organizations listed in the previous paragraph or through continuing education and private emergency management consulting companies.

If possible, audits should be conducted by a team of auditors who have training and knowledge in the areas to be audited. A team approach brings more experience and expertise to the proceedings and thus provides a greater benefit for the organization being audited. The audit team should have a clear leader, who will organize and guide the audit process.

e-Audits

Developments in information technology and assurance have made possible the practice of electronic auditing, which can be defined as an audit in which electronic means are used to collect audit evidence. Methods can be developed for constant real-time monitoring of electronic information and processes related to crisis management and emergency preparedness, and systems can provide notifications when anomalies occur.

There are clear benefits to using e-audits, including increased efficiency, reduction of audit errors, and introduction of real-time monitoring to enhance audit methodology.

Avalanches and Landslides

In the El Niño storms of early 1998, the U.S. Geological Survey (USGS) documented approximately $150 million in losses from 300 landslides that occurred in the California area. The 2006 landslide in the Philippines caused about 200 deaths, and about 1,000 people disappeared in the debris. Similar disasters also affect developed countries such as Japan, where approximately 3,000 people have been killed by landslides over the last century. Most landslides have occurred in Asia; however, the costly landslide damages have occurred in Europe (Table 1). Landslides and avalanches are the most destructive disasters in developing countries, particularly those with high population growth, intensive land use and deforestation, and construction and mining activities. Central America, northwestern South America, the Caucasus region, the Himalayan belt, Taiwan, the Philippines, Indonesia, Italy, and Japan are among the landslide hazard hot spots.

Mass Wasting Hazards

Landslides are external geologic processes called "mass wasting." Major causes of mass wasting are the downslope movement of rock under the force of gravity, slope angle, weakness in the structure and composition of rock (weathering), storms or heavy rain for periods of time, snow melting, human activities on slope, erosion of slope toe, deforestation loading or dredging, construction of roads, and mining.

If the mass moves along a curved surface of rupture, the movement is called slump. Usually, slumped material does not travel fast nor very far. If the material involved in rapid downslope movement is a large amount of water-saturated flow, the event has a disastrous effect on people and property. During the extremely fast mass movement, called an avalanche, rock debris along with ice and snow can move downslope at speeds of 200 kilometers (125 miles) per hour, causing a destructive event. Rock slides occur when blocks of bedrock break loose and slide downslope. Such events are among the fastest and most destructive mass movements. Rock slides tend to be most active during the spring, when heavy rains and melting snow are greatest.

Earthquakes also often trigger rockslides. The 1811 earthquake at New Madrid in Missouri caused landslides in the area of more than 13,000 square kilometers (5,000 square miles) along the Mississippi River valley. In terms of property damage, the most devastating effects of the 1964 Alaska earthquake were landslides in Anchorage, some 130 kilometers (80 miles) from the center of the quake. The earthquake triggered landslides of various types and dimensions, causing extensive damage to settlements, farmlands, and infrastructures. In addition to killing people outright, they can also have an extremely serious impact in terms of hampering rescue operations. Landslide activity can cause damage to communication and power networks, and the increased amount of sediment production and movement can also cause many problems.

Mudflow is a rapid type of mass movement that is most characteristic of canyons in semiarid mountainous regions that usually have little or no vegetation and involves a water-saturated debris flow during a large, heavy rain. The rapidly moving dense mudflow can push and carry large boulders, trees, and even houses long distances. The hot materials from the volcano cause rapid melting of great amounts of snow. Such saturated debris flow was also triggered by the volcanic activity of Mount St. Helens in 1980. “Earth flows” occur in humid areas as a result of excessive rainfall. Earth flows are quite viscous. They generally flow more slowly for a short distance downslope, unlike mudflows.

“Creep” is a type of mass movement that involves the gradual downhill movement of soil and may be initiated if the ground becomes saturated with water. Although the movement is slow, its effects are easily recognized. Creep causes fences and poles to tilt, and tree trunks are often bent with the movement.

The steep, narrow continental margins are also highly affected by slope failure processes. Downslope movements of dense mass movement eroding and transporting materials with high speed along the continental slope and rise are perhaps triggered by earthquake activity. In 1929, off the coast of Newfoundland, seismic activity had caused multiple breaks and the breakage of 13 transatlantic telephone and telegraph cables. The avalanche of sediment raced downslope with a speed approaching 80 kilometers (50 miles) per hour on the steep slopes, snapping the cables in its path.

Submarine slides are common and very efficient mechanisms of sediment transfer from the shelf and upper slope to deep-sea basins. They can occur on very gentle slopes, and they have the potential for triggering a tsunami. For instance, steep submarine scarps (15 degrees) of the Marmara Sea, marked with deep basins bounding with continuous sediment transportation via submarine canyons, carry a high risk associated with a large-scale slope failure to generate tsunamis and severe damage along the coastal area of Istanbul.

The tsunami generated by the earthquake-triggered Grand Banks slide in 1929 killed 27 people in Newfoundland. The 15-meter-high tsunami that killed more than 2,000 people in Papua New Guinea in 1998 was also a result of an earthquake-triggered huge submarine slide. The enormity of the Storegga slide, which took place 8,200 years ago, makes it one of the largest submarine slides along the coasts of Norway, Scotland, and the Faeroe Islands. Large submarine slides may again generate tsunamis with the potential for severe damage along coastlines, where oil production from offshore fields is ongoing in the Norwegian margin, Gulf of Mexico, offshore Brazil, the Caspian Sea, and west Africa. Another example is the land failure along the shelf edge at the Nice airport in 1976. Nuclear power plants are often located

Table 1 Landslide damages between 1903 and 2006

	Number of events	Killed	Homeless	Affected	Total affected	Damage, $ (000s)

in such coastal areas. Depending on the volume of deposits, submarine landslides can generate tsunami waves that can affect an entire basin.

Hazard Mapping and Monitoring

Movements such as rockslides and "rock avalanches" are the most catastrophic events of mass wasting. Since these events kill thousands, there is a need for intensive sustainable mitigation measurements, so that, through more effective and timely warnings, monitoring, forecasting, and better risk reduction, lives can be saved.

The Disaster Relief Act of 1974 delegates to the USGS the responsibility to map both flow source areas and existing landslides and to issue disaster warnings for landslides and other geologic catastrophes within the scope of this Local Hazard Mitigation Plan. The USGS has traditionally focused its landslide hazards research in specific geographic areas, such as the Pacific Northwest or southern California. The USGS and its partner, the National Weather Service, developed debris flow warning systems. The USGS has committed to assess the potential for hazard, to identify infrastructure that may be at risk, and to measure real-time precipitations aided by radar data. Warnings are broadcasts through the Advanced Weather Interactive Processing System (AWIPS) to local emergency managers and the media.

Landslides do not only kill people; they can also have an extremely serious impact in terms of hampering rescue operations and the delivery of assistance and can cause long-term damage to communication and power networks. The increased amount of sediment production and movement can also cause many structural and nonstructural problems.

It is also common that landslides do not occur as one singular event but may be induced by earthquakes and volcanic eruptions. Furthermore, landslides can also trigger other disasters such as floods, debris floods, and tsunamis. Therefore, mitigation of other disasters related to landslides should also be integrated into the local/national slope master plan.

The key factors in a comprehensive and integrated disaster management system are hazard and vulnerability identification, risk assessment, and risk mitigation. Generation of "landslide maps" is a core component of risk reduction initiatives and of great significance for assessing the landslide risk in terms of pointing out past and current landslide occurrences, identifying expected damage or losses by landslides, estimating landslide frequency, and risk reduction programs. The USGS produces basic types of landslide maps in California: landslide inventory maps, landslide hazard maps, landslide risk maps, and landslide zone maps.

The national slope master plan should provide crisis management using risk assessment, risk management, and risk communication (Figure 1), with the appropriate standard operating, early warning, evacuation, and rapid (post-disaster) information supply, and needs assessment procedures to support relief and efforts at building back better at the response stage.

B

Backup Facility

A backup facility is used like a backup generator when power is lost; it is something to turn to when the primary source is no longer available or accessible. A backup facility is also known as an alternate facility, alternate workspace/place, or emergency operations center (EOC). It is a location that a corporation turns to when access to its primary site fails to provide critical systems and services and is no longer accessible or available. It is activated only when a major crisis or disaster prevents the business from continuing normal operations. A backup site is key to a crisis management team (CMT) if it intends to restore and recover systems and services. The backup facility can be used by technology teams or end users, or as a space for the CMT, as a command center. It can also be any combination of these.

It is used to reestablish core or critical systems and services so that the impact to clients, customers, vendors, and suppliers is minimized and allows the corporation to get back to operations faster than if no alternate (backup) site were available. For crisis management teams, a backup facility provides the ability for other team members to perform their restoration and recovery efforts in the absence of the primary facility. If the primary site becomes unavailable, then there is another facility where workers can go: a contingency site.

There are three kinds of backup sites that can be utilized by a team: a cold site, a warm site, and a hot site.

Cold site: Simply put, this is an empty shell; it cannot be used for anything until resources are acquired and set up (both information technology (IT) and end user items). There is no data here, no IT, no resources of any sort. It is an empty space where organizations can go and begin to populate and set it up for operations when the need arises. To use an analogy, a cold site is like an empty glass compared to a full glass of water.

Warm site: This site may have some physical equipment available, with some wiring in place. It could be limited in space for end user use, but there is a wait required while additional equipment is loaded and configured before it can be utilized. One of the main components that differentiate a warm site from a hot site is that data are not available at a warm site. The warm site must wait for data to be restored and, possibly, user workstations to be connected to a network before any activities can commence. A warm site is like a half-full glass of water compared to a full glass.

Hot site: A hot site is identical to a primary site; it is ready to continue operations almost immediately and often is set up to "fail over" without any human intervention. It contains equipment that has a duplicate set of data—copied at very regular intervals—and systems (i.e., networks, servers, etc.) preconfigured to allow operations to continue. This site can house everything from technology systems to end user desktops and desks. A hot site is like a full glass of water beside another full glass of water.

All three of these backup site options can be broken down into two categories: internal sites and external sites.

Internal: An internal backup site is under the direct management control of the corporation and can be used by the corporation for any purpose.

External: An external backup facility is not under the direct management control of the corporation. Most notably, this is a facility operated by a third-party vendor who has a contract signed by a corporate executive (or even members of the CMT) to provide cold, warm, or hot site services.

The decision to use a backup site comes from the crisis management team at the time of disaster—depending upon the impact—or after a triage discussion (aka an impact assessment) has been performed. If the decision is made to move operations to a backup facility, the CMT then ensures that appropriate communications are disseminated, including vendor, media, the general community/public, supplier, and employee notifications.

A backup facility, either cold, warm, or hot version, is necessary if a corporation or a community leader is to reestablish operations; without any alternate site available, it is nearly impossible to become operational after a disaster.

For instance, if a hot or warm backup facility is available to a corporation or community leadership when a disaster or crisis strikes, it is able to put into action restoration and recovery efforts that will enable critical services to become available sooner than if a site did not exist. If only a cold site exists, it will take longer for services to become available, as teams will be “starting from scratch.” It also means that the CMT will be busy making initial decisions on what to restore first and foremost, but these types of decisions have already been made when a warm or hot site is first established.

The decision as to which kind of backup facility is required is determined when internal impact assessments are completed; the resulting findings can have a positive or negative impact on the CMT. Not having a site to fall back to can mean that an organization can take too long to restore services, which may make partners—and the community—angry waiting for services to be restored. A backup facility that already has some functionality available to the CMT can enable it to be operational sooner, which can only benefit those impacted by the disaster or crisis and in need of core critical services.

Backup Media

The purpose of backup media is to store information for future restoration and use, much like a spare tire is a backup for a tire gone flat. Backup media can take many forms, but the form used needs to be suitable for the restoration process and the restoration environment. Backup media are important to the crisis management process in that having a way to restore the information that existed before the crisis can help the response to and recovery from the crisis.

First Steps

The first step in selecting backup media is to find backup media that can be used by existing equipment to perform the backup and also the restore. The media should be readily available on the open market and not prohibitively costly to use. Media can be reusable, but if they are reused, they must only be reused per the manufacturer's reuse specifications and they should be restored periodically to be sure they areworking properly.

Most equipment capable of using information comes equipped with devices for "reading" new information into the equipment, and sometimes those devices can also be used to "write" existing information out to the same type of media that they are read from. Of course, sometimes the devices are "read only," which means they can only read and cannot write.

Using personal computers (PCs) as an example, they usually come equipped with several ways to read information using different portals on the PC. Some devices on a typical PC include a compact disc (CD) and a digital video disc (DVD). These have drawers that open to accept plastic reflective discs that spin around to be read, much like a record player or an old Victrola. Some CD and DVD devices can also write to blank discs. Unless the disc is rewritable, it cannot be written to a second time. Another device is called a memory stick that plugs into a portal on the PC called a universal serial bus (USB). These memory sticks have no moving parts and are usually small, sometimes called "thumb drives" because of their similarity to the size of a person's thumb.

Media Types and Storage

The two different types of media, CDs and memory sticks, represent two major ways of storing information. CDs and DVDs store information optically, which means the information is read and written using lasers in the CD/DVD drive. The memory stick stores information magnetically or electronically. Each has its advantages and disadvantages. A CD is damaged by heat and ultraviolet light or anything that would deform the plastic disc or inhibit light from passing through its protective plastic outer layer. Memory sticks can be damaged by a strong electrical charge like a power surge or a strong magnetic field or multiple passes through high power X-rays in airport luggage screeners. Both media can survive water, but the electronic media should be unplugged prior to being exposed to water or they could short-circuit. Electronic media need to be dried out over a longer period of time, while optical media can simply be cleaned and used.

In 2009, the National Oceanic and Atmospheric Administration (NOAA) completed implementation of its nine-year, $180 million contract by installing the newest generation of IBM supercomputers (Stratus) and backups (Cirrus). The system and backup will allow the NOAA to run more complex models to extend watch and warning lead times for severe weather. Housed at separate locations, the perfectly symmetrical pairing allow Cirrus to take over in a matter of minutes in the event that Stratus fails.

The environment where the media will be used helps determine the type of media to use. If the media will be exposed to heat and scratching, then magnetic media should be used. If the media are exposed to magnetic fields and potential power surges or frequent X-rays, then optical media should be used. In some cases it may be a good idea to use both media. No matter which media are used, it is always a good idea to back up information periodically and keep at least one of those backups in a separate location from the others, often called an off-site location. For PCs, this off site can be a safety deposit box or a lockbox at a distant site. For business media, any vendor specializing in off-site storage can be contracted with to protect the media. It won't do much good to have backups if they are destroyed with the original information. The following are several different ways to back up and store media:

Internet backup: Another way to provide protection for data is to use an Internet backup service and back up information far away on media protected by the service provider. It does not really matter which media the vendor uses because the information is stored far away from whatever might destroy the original information. A new PC connected to the Internet can be used to restore the lost information.

Read-only media: If computer viruses are of concern, then read-only media should be used. Optical media can allow a backup to be written once but not allow anything else to write over the information or to erase the information. Some electronic storage can be locked so that nothing can write to it until it is unlocked.

Noncomputer media: Backup media do not have to be computer based. Papers can be backed up by making copies and storing them off-site in a safety deposit box; or businesses, there are also off-site paper storage vendors who provide climate-controlled, secure warehouses. Papers can also be scanned as images or pictures and stored electronically. Imaged papers do take up considerably more storage space than just the information on the paper, so consideration should be given to cost per page. An older form of storing papers and images is called Microfiche; it is essentially the mass scanning and storage of small pictures of the documents that can be viewed with a special Microfiche reader that magnifies the images.

Magnetic tape: There is a more business-oriented medium called magnetic tape that uses strips of tape with a film that can be magnetized to hold information. These tapes are subject to the same considerations as other magnetic media but in addition, rough handling can damage the mechanism holding the tape and can even crinkle the tape itself. Another device is an external hard disk drive that is much like the hard drive on a PC, but it is encased and plugs into a computer, usually via the USB plug.

Media Attrition

As time passes, media can become outdated and may not be readable by newer media readers. As time progresses and new backup media are developed, serious consideration should be given to converting existing backups to the newer media, as well as to using the new media for current backups. Nothing could be worse than going to get important information from older backups and finding that there is no longer the capability to read the older format or the older media. The retention of older backups and when they should be converted to newer technology or destroyed always needs to be considered.

Conclusion

There are many forms of backup media that are either optical or magnetic. The possible threats to which media might be exposed should determine which medium are used, or if different types of media should be used. Periodic backup on the media of choice is required to ensure several versions of information just in case one medium is destroyed or cannot be read properly. Older media backups need to monitored so that they can be destroyed or converted as newer media replace older media. Some media backups should be stored off-site to protect them from harm. Planning for the proper backup media can help crisis management speed recovery and get the organization back into operation.

Backup Strategy

The purpose of a backup strategy is to create and maintain the ability to recover data that are required to perform one or more necessary functions. Prior to designing a backup strategy, the functions must be prioritized, the required data identified, and the recovery objectives defined. After these data requirements and recovery objectives are defined, a backup strategy can be determined that will meet the recovery objectives. After the backup strategy has been approved and implemented, the processes are tested regularly to ensure they will work properly when needed. Crisis management processes invoke the recovery processes that use the backup strategy.

Business Impact Analysis

Necessary functions are identified using a business impact analysis (BIA). The BIA lists the functions performed and prioritizes them in order of most important to least important. Along with the BIA are financials that state the various costs of all functions not working. Quantifying how much revenue will be lost or how much cost will be incurred while waiting for the data to be recovered helps determine how much to spend on the data recovery processes. Typically, the higher priority a function has, the more its absence will reduce revenue. Conversely, functions with a low priority typically do not garner much revenue or cost much to be without for extended periods of time. Of course, when this information is presented, it is up to the highest-level decision makers to conclude how much they are willing to spend on data recovery to mitigate the identified losses. With an approved spending threshold, the data recovery processes can be determined. At times, the data cannot be recovered within the approved spending threshold. If that happens, the decision makers must decide whether they want a longer recovery time objective (RTO) and recovery point objective (RPO) to avoid the cost of data recovery or to provide additional spending to accomplish proper data recovery. Care should be taken when a function is deemed unnecessary, as most businesses do not spend on unnecessary functions; they will expect that function to eventually be recovered.

Recovery Objectives

Recovery objectives include the recovery time objective (RTO) and the recovery point objective (RPO). The RTO is the length of time a function can operate without the data, and the RPO is how old the data should be when they are recovered. Another determination is the RTO for each function; usually, the more important the function, the shorter the RTO. Then the RPO is determined by understanding the maximum age of the data that must be recovered. Functions may not continue if they must start again with recovered data that are too old. The RPO also helps determine the backup and restoration processes that must be used. Typically, the shorter the RTO and the RPO, the more expensive data recovery will be. This is why the financials discovered in the BIA are important: to provide a cost-to-loss comparison to solidify the spending threshold. With the entire set of requirements and objectives from the BIA and the spending threshold, the backup strategy can be designed. Again, longer RTOs and RPOs allow less expensive backup strategies, while shorter RTOs and RPOs require more expensive backup strategies.

Designing a Backup Strategy: Backup Types

The backup strategy must have the proper environment meeting the spending threshold and the

RTOs and RPOs. There are many aspects of the backup environment that should be understood if someone fluent in technology will not be used to assist in the design.

Data typically are stored in data records that contain pieces of information such as name and address. These data records are stored in data files that represent the current state of all the data they contain. The process is based at the record level. A record is read into a temporary area, that record is changed, and that temporary record then replaces the record in the file. Databases are another way to store data. Typically a database works on parts of records called fields, making it faster because only the field is changed, not the entire record.

Traditionally, there are two main backup types: a full backup that copies everything and can be used to recover everything, and incremental backups that are used between full backups to capture changed files. Full backups tend to take much longer to perform than incremental backups, but incremental backups have only changed data from the last full backup, and each incremental backup must be recovered over the previous full backup to bring the data up to the latest incremental backup. This can lengthen recovery times because the full backup and then all the incremental backups need to be recovered rather than just the latest full backup. In addition, if one incremental backup is damaged, all the subsequent incremental backups cannot be used.

Another type of backup is an intermediate backup. Intermediate backups are usually temporary backups to protect data during updates. For example, at the beginning of the day a temporary backup is made, the daily work is completed, and, once the daily work is verified as being accurate, the last intermediate backup is recycled. This allows any mistakes or intentional malicious manipulation of data to be eliminated by taking the correct information from the intermediate backup.

Databases provide similar backups. A change is made to a field and that change is stored in a log that shows the original data and what those data were changed to. This can be very powerful because the logs can be used to select specific changes to back out if something in the data is wrong. Databases are typically backed up in a similar manner. A database full backup is done and then the log files are backed up to provide a way to use the logs files to roll data changes forward or backward from the last full database backup.

Backup Environment

The backup environment has several different characteristics, networking connectivity to the backup environment (synchronous or asynchronous) and the backup format (character or block) and backup engine (mirroring, replication, etc.).

There are two types of networking for backups: one is called synchronous and the other is asynchronous. Synchronous has a direct connection to the backup environment to maintain constant or synchronized communication that can involve expensive network connections of high capacity. Asynchronous consists of backed-up data that are stored temporarily in an appliance and sent to a like backup-location appliance using a smaller capacity network that is less expensive. Backups take longer to reach their final destination, but they consume less network capacity.

There are two types of backup formats: either block or character. Block formats take data in larger chunks of data that take less time to process but hide the data inside from being used as a way to manage the backups. Character formats allow the use of each character to manage the backups, but they take longer to process.

Following is a discussion of the different types of backup environment engines that can be used to design a backup strategy.

Mirroring sends a character for character mirror image of data synchronously to a backup location that can be either on-site or off-site. Mirroring is typically used to get large amounts of data backed up so that data can be used as if they were a direct copy, or mirror image, of the original data. Of course, the mirror image data are not stored backwards, as if by a reflective mirror.

Replication sends data blocks synchronously, usually off-site, directly to a storage device and can also send data blocks asynchronously, usually off-site, using some replication appliances for intermediate storage of the blocks of data so they can be transmitted off-site using a less expensive network connection.

De-duplication sends only changed data blocks either synchronously or asynchronously off-site using de-duplication appliances to manage the data blocks. Since only changed data blocks are transmitted, the amount of data is greatly reduced, saving transmission costs.

Taking a snapshot of a disk stops processing on the disk and sends a complete copy of the disk synchronously to another storage device, usually at the same location. Rolling or continuous snapshots send data off-site asynchronously.

A long-standing backup strategy is magnetic tape backup. Tape drives are attached to a server specifically designed to perform backups, and all the other servers run a small application called a "client" that allows each server to back up through the backup server. The tapes are changed when they run out of room, and then the full tapes are sent via mail or delivery vendor to an off-site location. The off-site location is usually climate controlled so that humidity does not form water droplets on the tape.

Storage as a Service

There are also vendors who provide Storage as a Service (SaaS), which eliminates the capital expense of equipment and allows purchase of storage based on amount needed. Two of these services are called dispersed storage and cloud storage. A business with several locations can also buy the software and hardware to be its own SaaS provider.

Dispersed storage is a single copy of the data stored across multiple locations in such a way as to allow the reconstruction of one location's data from data at the other locations. This limits the duplication of data without sacrificing the ability to recover lost data. This environment is used by many to protect production data and is really not a traditional backup, because a full duplicate of the data does not exist. Dispersed storage can be used to eliminate disaster backups, but it requires incremental backups to be very strong in case data are corrupted by malicious intent or computer viruses, and it may not be possible to recover from a full backup.

Cloud storage is normal storage provided over the Internet by technology companies that buy hardware and network capacity to provide storage capacity for their customers. This fits into a backup strategy in that data are not located in the primary workplace and so systems are safe from any threat and are protected. Professional data security experts should be consulted before moving to the cloud to ensure the cloud vendor has appropriate processes to meet security requirements for that particular industry. The physical equipment must be protected, the software must have security, the network must be secure, and the vendor must have a process for breaches of security; SAS70 certification is also important.

Other Storage Terms

Some other useful means of data storage include online storage that is always synchronous and used by people in real time. Near-line storage is usually synchronous and used in real-time as slower archival storage. Off-line storage is usually asynchronous and is done on tapes or other media that cannot be accessed immediately. Off-site storage is always asynchronous and takes place on media that can be taken off-site for protection and recovery.

Encryption is an important consideration for a backup strategy. Encryption encodes the data on the backup using a protected key so it cannot be read by anyone else unless they have the key. Without encryption, anyone with the same technology can read backups. Most financial and health care regulations call for the encryption of all backups containing client and patient information. Encryption creates a safe harbor from litigation. The saying is to encrypt everything.

Backup Strategy Using Recovery Objectives

Very short RTOs and RPOs make it necessary to design a high availability (HA) environment where data are used or stored in two or more geographically separate locations at the same time. HA environments allow any single location to be destroyed with little to no loss of data and time. Of course, the people performing the function must also be HA so the entire staff is not disabled with the single location, leaving no one to perform the critical function. HA environments typically use strategies such as SaaS, dispersed storage, and bunkers.

Short RTOs and RPOs provide some more options in design. The HA could still be used if the RTOs and RPOs are too short for other strategies. There are backup processes called replication that back up data from one location to another location called a "hot site," with dedicated equipment ready to be used. When the original location goes down, the replicated data at the hot site can come online in the amount of time it takes to bring the systems up using the replicated data. Recovery would happen in minutes to hours.

Medium RTOs and RPOs allow backup and recovery at more moderate expense. Knowing the amount of data to be recovered helps as well. Many backup and recovery options have estimates of backup and restore data transfer speeds. This makes it possible to estimate the amount of time it will take to back up and also restore the data during recovery. For example, if the data transfer rate is 3 billion characters per minute and the data to restore amounts to 300 billion characters, then the restore will take about 100 minutes. If the data transfer speed meets the RTOs and RPOs, then the design will work well for the recovery. When designing backup strategies for data recovery in the medium RTO and RPO range, a "warm site" could be used. A warm site is an alternate location with equipment in several different states of readiness. In many cases the fastest tape backup and restore devices can be used to recover data, enabling recovery in one or more days.

Longer RTOs and RPOs offer even more choices. A "cold site" is an alternate location with no powered-up equipment and is often an empty shell of air-conditioned raised floor space. The use of a cold site is the least expensive choice, other than doing nothing, but again, it requires RTOs and RPOs of days or longer. The option of preconfigured equipment shipped quickly to the cold site can provide an affordable recovery option. Here again, tape backup and restore is often used and even slower, less expensive devices can be obtained to hold data. Long RTOs and RPOs may allow systems to be re-created from the installation media and either reentering data or starting fresh, entering older data by hand as time permits.

Case Study: Health Care Industry Backup

A company that hosts computer software for health care clients with 24/7 operations had a backup strategy that allowed recovery of critical systems within 24 hours from tapes stored offsite at a warm site.

The health care industry received new government mandates that required more stringent controls on health information and more consistent delivery of patient services like medications. As the clients requested additional software products and more online real-time access to these systems to meet the mandates, there was a shift in the recovery requirements that also changed the backup requirements.

The government health care mandates pushed the health care information onto computer systems from paper and, because the information was no longer on paper, the recovery objectives were shortened to hours to avoid the problem of, for example, not being able to deliver medications because computers were down.

The business continuity life cycle (BCLC) was initiated to address the shortened recovery objectives, and the results changed the backup strategy from tape backup and recovery at a warm site to a warm site with asynchronous data replication. This backup strategy allowed data to be sent to an alternate location with equipment that could be started up and running within a few hours so that clients could provide critical services such as medications while still meeting government-mandated treatment of health care information.

Bunkers

One final option is to avoid losing data and also avoid having the cost of equipment just for backup and recovery. One choice that meets these criteria is known as a bunker. Just as the U.S. military uses bunkers to protect assets, a business can use a bunker to house its existing systems and data. Because the bunker is impervious to all natural hazards and most human-made hazards, there is only the need to purchase equipment used on a daily basis. No extra cost for backup equipment for alternate site recovery is needed: no HA site, no cold site, no warm site. The only drawback is that everyone must access the site through network connections that may go down. But redundant connections and redundant network vendors coming into the bunker can enable a quick switchover to an alternate network vendor.

Backup Media

Some other things to consider are the different forms of backup media. There are two major types of backup media: optical and magnetic (electronic). The possible environmental threats that the backup media would be exposed to should help determine which media are used. Optical media tend to store data on reflective material in a plastic substrate such as compact discs (CDs) and digital video discs (DVDs). These optical media are susceptible to damage from scratches, heat, and ultraviolet rays from the sun over prolonged exposure. Magnetic media such as tapes and external hard disk drives (HDD) are susceptible to electric surges and strong magnetic fields as well as string X-rays that may be found in airport baggage scanners.

Older media backups need to be monitored so that they can be destroyed or converted as newer media replace older media.

Some media backups need to be stored off-site to protect them from harm during disasters. There are many off-site storage vendors who even have climate-controlled storage rooms to prevent condensation from forming within the media containers and damaging the media.

Exercising Backup and Recovery

After the backup strategy has been approved and while it is being implemented, there should be activities to develop periodic testing of the backups to ensure those backups can actually be recovered; this is commonly referred to as disaster recovery testing. Typically, disaster recovery tests are performed several times each year and the results used to enhance the recovery process.

Conclusion

The purpose of a backup strategy is to create and maintain the ability to recover data that are required to perform one or more necessary functions. Prior to designing a backup strategy, the functions must be prioritized, the required data identified, and recovery objectives defined. After these data requirements and recovery objectives are defined, a backup strategy can be determined that will meet the recovery objectives. The strategy should design the backup (and recovery) environment based on the RPOs and RTOs and the cost threshold identified by decision makers, as well as the proper backup media. After the backup strategy has been approved and implemented, the processes are tested regularly to ensure they will work properly when needed. The processes resulting from the backup strategy are invoked from the crisis management process.

Bankruptcy, Corporate

Bankruptcy laws provide part of the legal context in which businesses operate because they specify how a failed business, or a business that cannot meet its financial obligations, will be treated in court. Bankruptcy laws (which may include principles based in common law as well as statutes) provide guidelines for courts to examine and weigh the claims of creditors, value the assets of the business, direct how the assets will be distributed among the creditors, and possibly cancel some of the debts. Bankruptcy laws vary considerably from one country to the next, reflecting the differing attitudes different societies hold toward bankruptcy and related issues such as the relative importance of promoting risk-taking versus prudence.

Bankruptcy laws are essential to the functioning of a modern business environment because they establish rules that set the framework within which loans are offered and accepted and thus promote credit and business growth. Ideally, bankruptcy laws recognize the claims of both the debtors and the creditors and treat everyone fairly. When a business venture goes bad, the bankruptcy laws allow those involved in a failed enterprise to make a new start and see that whatever assets are available for distribution are shared fairly among the creditors. In the context of crisis management, understanding the process of bankruptcy is critically important, as it is a form of regulatory risk. For example, if a company is forced into bankruptcy as part of a crisis, and it is not up to date on how to follow the law, it is in a position to make the situation worse, potentially losing more money to fines, unprotected assets, and the like.

Attitudes toward bankruptcy have changed over time and vary across societies. In ancient Greece, indebted persons and their families were sometimes forced into debt servitude, working with no pay until their debts were paid off. In the Middle Ages, debtors in some countries were maimed, publicly flogged, or imprisoned; these practices were focused on deterring bankruptcy, which was seen as a kind of fraud, rather than on enabling the debtor to discharge the debt. In addition, debt was commonly viewed as the responsibility of an individual, even if it was a business that went bankrupt. However, today the bankruptcy laws in many countries, including the United States, also recognize the value of allowing a bankrupt person or company to make a "fresh start" after a business failure and thus have made the consequences of a bankruptcy less severe for the debtor.

U.S. History of Bankruptcy Law

In colonial America, bankruptcy laws were influenced by English law and provided severe punishments for bankruptcy, up to and including death. To settle debts, all of the assets owned by the debtor could be seized by the court and liquidated, including the tools the debtor used to make a living, thus making it very difficult for a bankrupt person to get back on his feet again; if the debtor tried to conceal assets during the bankruptcy process, he could be executed. American bankruptcy law continued to be heavily influenced by English law into the 19th century, although different states were allowed to have different laws, resulting in some provisions that seem eccentric to modern eyes, such as giving American creditors preference over English creditors, or giving preference to creditors within the state where the bankruptcy was filed, as opposed to creditors from other states.

The federal Bankruptcy Act of 1898 included several major reforms: it contained provisions to restructure debt, it allowed states to decide which of a bankrupt's assets were exempt from distribution, and it provided for equitable distribution of the bankrupt's assets to creditors. This law set the context for bankruptcy in the United States for the next century and made the prospect of filing bankruptcy much more attractive: most bankruptcies in the United States before 1898 were involuntary (initiated by the creditors), but since 1898 most business bankruptcies have been voluntary (initiated by the debtor).

Current U.S. bankruptcy law is based on the Bankruptcy Reform Act of 1978 and is codified in Title 11 of the U.S. Code. Title 11 allows for six types of bankruptcy, and these types of bankruptcy are often referred to by the chapters of the code in which they are described. The most common types of bankruptcy are Chapter 7 (liquidation) and Chapter 11 (reorganization); Chapter 9 refers to municipality bankruptcy, Chapter 12 to bankruptcy for family farmers or family fishermen, Chapter 13 to individual debt adjustment, and Chapter 15 (added in 2005) to bankruptcies involving more than one country.

Current Bankruptcy Law in the United States

Today, bankruptcy in the United States is governed by federal law, and bankruptcy cases can only be filed in federal courts; state courts have no jurisdiction over bankruptcy, although they may differ in matters such as which assets of a bankrupt company or person are exempt from liquidation. There are 90 bankruptcy courts in the United States, with at least one in each state. The most common type of bankruptcy is Chapter 7 bankruptcy, also called liquidation. Under Chapter 7, the court appoints a trustee who takes over the debtor's assets (with certain exemptions for essential property), reduces them to cash, and distributes the cash to the creditors. Companies filing for bankruptcy under Chapter 7 go completely out of business, and usually individuals holding shares of the company's stock lose their entire investment.

SKYLINE DISTRICT
1400
Smith
Bell

The former Enron complex on 1400 Smith Street in Houston, Texas, which Chevron took ownership of and occupied in 2011. On the morning of October 26, 2001, Enron workers arrived to find the surrounding avenues blocked and cordoned off by police because of an overnight terror threat. It was a false alarm, but the real crisis was already in progress inside: as an enormous accounting scandal unraveled, Enron's stock prices quickly collapsed, resulting in fraud convictions, destroyed reputations, and bankruptcy.

Most businesses filing for bankruptcy in the United States do so under Chapter 11, also called reorganization. Chapter 11 allows a business to continue operation under a plan of reorganization approved by the court, while paying creditors over a period of time; in addition, some debts may be discharged (allowed to go unpaid) and some contracts terminated under Chapter 11. To initiate the proceedings, a debtor files a petition including a disclosure statement containing information about the business's liabilities and assets, and a plan of reorganization, including classifying the claims involved and how each will be paid; creditors are allowed to examine this statement, but the court has the final word on whether or not it will be accepted.

When a company files for bankruptcy, there is often not enough money to pay all the claims of all the creditors. Normally, secured creditors, such as banks, have first priority. Unsecured creditors, such as suppliers and bondholders, are the next priority, and stockholders have the weakest claim on the company's assets; if the secured and unsecured creditors do not receive the full value of their claims, the stockholders may receive nothing (their stock becomes worthless). Although a company in Chapter 11 bankruptcy may continue to be traded (although not usually on the New York Stock Exchange or NASDAQ), they are a risky investment because the shares may be canceled as part of the reorganization, and even if they are not, stockholders are a low priority when the company's assets are distributed. When a company emerges from bankruptcy, it may have two types of common stock traded: the old stock that was on the market when the company went into bankruptcy and a new common stock issued as part of the reorganization.

Although corporate bankruptcies are often highly publicized, due to the fame of certain companies and the large amounts of money involved, most bankruptcy filings by the United States are individual, rather than business, bankruptcies. According to data reported by the American Bankruptcy Institute, since 1980, the percentage of bankruptcies in the United States filed

Case Studies: Notable Corporate Bankruptcies

Continental Airlines filed for Chapter 11 bankruptcy reorganization twice, on September 23, 1983, and again on December 3, 1990. Continental had been acquired in 1981 by the Texas Air Corporation, controlled by Frank Lorenzo, and in 1983 was suffering financially due to deregulation (meaning that had to compete with other airlines based on price) and the recession. However, Lorenzo was also involved in struggles with the labor unions representing Continental's workers; he argued that the company would not survive unless they accepted layoffs and reduced wages but was unable to achieve the changes he desired through negotiation.

As part of Chapter 11 reorganization, the company was freed from its obligations under the old labor contracts, and new contracts were drawn up that were substantially less favorable to the workers; due in part to the Continental example, federal law was later changed to make it more difficult for companies to use bankruptcy to cancel labor contracts. The company emerged financially sound from Chapter 11 in 1986. On December 3, 1990, Continental again filed for bankruptcy; factors contributing to the company's financial difficulties included increased fuel prices due to Iraq's invasion of Kuwait on August 2, 1990, and debt incurred by Lorenzo's aggressive policy of expansion. Continental emerged from this second bankruptcy in 1993 and continued to function as a profitable airline.

When the Enron Corporation filed for Chapter 11 bankruptcy reorganization on December 2, 2001, it was the largest bankruptcy to date in U.S. history. Enron began as a natural gas supplier but in the 1980s became more focused on creating markets rather than providing products or services; for instance, Enron made an estimated $1.5 million trading in electricity supplies during a power crisis in California from 1997 to 1998. Between 1998 and 2000, Enron was one of the most profitable corporations in the United States. However, Enron's stock price fell sharply in 2001, and it was later revealed that Enron executives had been selling their stock beginning in 1999 while publicly proclaiming the financial health of the company and using misleading accounting practices to hide its true financial condition. Numerous Enron officials were convicted on charges that included conspiracy and securities fraud, including CEO Kenneth Lay, President Jeffrey Skilling, and Chief Financial Officer Andrew Fastow. The scandal also destroyed the reputation of the accounting firm Arthur Andersen.

The financial services firm Lehman Brothers filed for Chapter 11 bankruptcy on September 15, 2008; the company held over $600 billion in assets, making Lehman's bankruptcy filing the largest in U.S. history. As an investment bank, Lehman was not subject to the same regulations as depository banks and was heavily leveraged with substantial investments in the housing market. Lehman profited during the housing boom of the 2000s but began to incur heavy losses in 2007 due to the subprime mortgage crisis. Despite evidence that the company was not doing well, Lehman's filing for bankruptcy shocked the financial world, and the Dow Jones average dropped over 500 points (a 4.4 percent decline) on the day Lehman filed. The Lehman bankruptcy also focused national attention on the issues of executive pay (e.g., CEO Richard Fuld received $484 million in salary, bonuses, and stock options from 2000 to 2008) that seemed to many excessive, particularly for someone in charge of a company when it went bankrupt.

by businesses peaked in the mid-1980s but has declined since then. In 1980, 13.2 percent of bankruptcy filings were by businesses; in 1984 (the peak year), 18.4 percent; in 1985, 17.3 percent; in 1990, 8.5 percent; in 1995, 5.7 percent; in 2000, 2.8 percent; in 2005, 1.9 percent; and in 2010, 3.5 percent. The number of businesses filing for bankruptcy in the period 1980–2010 peaked in 1987 and has fluctuated up and down during the period. In 1980, 43,694 businesses in the United States filed for bankruptcy; in 1985, 71,277; in 1987 (the peak year), 82,446; in 1990, 64,853; in 1995, 51,959; in 2000, 35,472; in 2005, 39,201; and in 2010, 56,282.

Ethical Issues in Corporate Bankruptcy

It is tempting to interpret bankruptcy on a moral level, with the bankrupt company cast as a reprobate that failed to meet its obligations to the creditor who was good enough to lend it money. This interpretation draws on the common ethical standard that all debts should be paid; bankruptcy laws violate this standard by allowing some debts to be dismissed or deferred. However, bankruptcy laws can be justified as a necessity in a modern economy, and most would argue that they increase the overall wealth of a society by allowing companies to take risks, and to resume functioning after a business failure. Bankruptcy laws also make credit more available to businesses because they assure creditors that debts will be discharged in a fair and orderly process should a business file for bankruptcy. Another argument in favor of regarding bankruptcy as part of the business environment, rather than a question of morality, is that anyone should recognize that every business venture involves risk, and lending money is itself a business and is therefore not a risk-free venture. Anyone in the business of making loans must allow for the fact that it is possible that the loan will not be repaid in full or on time; this is one reason lenders charge differing interest rates to different enterprises and also why they may demand collateral to secure a loan.

Some charge that the Bankruptcy Reform Act of 1978 allowed businesses to develop a new strategy, sometimes referred to as “strategic bankruptcy,” which can be seen as an abuse of the ethical principles that should govern business dealings. A company using this strategy may focus on creating high profits in the short term while incurring debt that it intends to discharge through Chapter 11. Persons ranking high in the corporate hierarchy may receive substantial bonuses based on the company’s short-term performance while concealing the true financial health of the company. In addition, misleading accounting practices may conceal the financial health of the company from the public, which believes the company’s stock is a good investment based on the information available to it. Because they have privileged information, people holding leadership positions in the company can sell their shares of a company’s stock while the price is still high, while ordinary shareholders will still be holding the stock when its value drops sharply (e.g., due to bankruptcy filing or the release of previously withheld information). Companies may also use Chapter 11 bankruptcy to get out of contractual obligations, for instance, contracts with labor unions.

The counterargument to these charges is that the bankruptcy code requires companies to fulfill their obligations as best they can and that the purpose of allowing companies to renegotiate contracts is to allow them to meet all of their obligations as best they can. By definition, an insolvent company cannot meet its obligations, and bankruptcy laws are intended to maximize assets and distribute them fairly in a less than ideal situation. Although it is true that not everyone has access to the same information or quality of legal advice (a fact true in most areas of life, not only bankruptcy proceedings), the law does not recognize these differences but requires that all claims be treated equally. In addition, anyone involved in business transactions, including unions negotiating labor contracts, must be aware that every contract includes the possibility that it will not be honored.

Biological Engineering Risk

Following the rapid evolution of biotechnology and genomics in the 1990s, with sophisticated efforts to manipulate and engineer recombinant DNA (deoxyribonucleic acid), the onset of synthetic biology (or SynBio) in the 21st century may have been seen as a natural result of prior scientific research. But now SynBio, as it is often called, goes beyond mapping genomes and manipulating genes to the point where scientists and graduate student microbiologists not only are examining how to build life from scratch, and merge or transfer genomic material between different species, but are also experimenting with every conceivable combination of nucleic and amino acids and engineering new life-forms.

This is a new iteration of genetic engineering taking place in commercial settings, on university campuses, in government labs, and within the privacy of creative people's own homes. In the name of scientific advances aimed at bringing the greatest benefits to the greatest number, the vast amount of SynBio work appears to be targeted at lengthening life spans, curing diseases, and helping solve intractable public health problems. All of this burgeoning creativity takes place in the absence of widespread societal debate and regulatory oversight. SynBio entails construction of new biological parts, devices, and systems not normally found in the natural world along with redesign of existing biological systems to perform specific tasks. In some cases, genomic material is being structured and combined with nanoscale technologies, moving life's basic ingredients around at the atomic and molecular levels. In the context of crisis management, these risks, both physical and through public perception, should be recognized.

Future Anticipation and Residual Angst

Researchers engaged in SynBio are convinced that, with enough knowledge, they will be able to write programs controlling genetic components, allowing eventual incremental adjustments to nature itself and, in so doing, guide and influence human evolution. The prospects and possibilities attached to SynBio are breathtakingly impressive and full of promise for the betterment of humankind. No recent scientific achievement has promised so much and yet contains significant ambiguous risks and disturbing implications for deliberate abuse, including criminal and warlike misuse.

But there is profound irony in a scientific endeavor that abundantly signals benefits while downplaying deliberate or inadvertent risks of abuse and misuse. Public perception plays a huge role in the overall societal acceptance and endorsement of SynBio, and it remains unclear whether there will be widespread public support for independent engineered cells becoming their own factory, producing new chemicals or new life-forms. Between tacit approval and universal endorsement by the public is a widely ambiguous zone of calculated indifference.

In a 2009 survey from the Wilson Center Project on Emerging Nanotechnologies, some 22 percent of adults indicate they have heard a lot or some about synthetic biology. But nearly half—48 percent—have heard nothing at all about the technology. Public ignorance of SynBio is an issue that needs to be examined because the governing assumption is that society acknowledges and supports all the myriad scientific programs, schemes, and projects under the banner of SynBio.

The origins of wider public angst are rooted in the concern expressed by some lawmakers, pundits, and press commentaries that the entire SynBio environment globally is essentially a "wild West" free-for-all environment with no ground rules, regulatory oversight, or periodic government scrutiny. It follows that opportunities for criminals, terrorists, and rogue dictators to devise SynBio tools and weapons in the future cannot be ruled out. Worse, any such weapon would likely confer the kind of strategic advantage to its owner that a dozen nuclear weapons provide. Because no cure, prevention, or vaccination against the SynBio designer disease can be effective, the owner has substantial power and strategic leverage.

Nevertheless, the global SynBio community has generally favored self-regulation. Public concerns about excesses in genetic engineering and patenting life-forms provoke the question of whether any metrics, standards, or special procedures can be developed to somehow govern the conduct of SynBio research and thereby foster a global commons of prudent risk management.

What Is the Risk Terrain?

It is natural to expect global commercial competition, the natural competition among sovereign states embroiled in security equivalence measures, and the pure desire among many scientists to garner Nobel fame for their work is sufficient to build a firewall against mischief and criminal behavior. Many sincerely believe this mechanism will provide a transparent avenue for SynBio to regulate itself. To get a better glimpse of the risk terrain attached to SynBio, we should look at one recent U.S. government effort to examine SynBio strengths and weaknesses.

The National Science Advisory Board for Biosecurity (NSABB) established a synthetic genomics working group in November 2005, and that group raised some significant concerns attached to SynBio that may pertain to select agents (SAs), which the government has designated as chemical-biological warfare agents to be monitored and thwarted. Members of the NSABB said that they had concerns concerning "the ease with which individuals versed in, and equipped for routine methods in molecular biology can use regularly available starting material and procedures to derive some SAs *de novo*." The NSABB also mentioned that SynBio "allows expression of agents that resemble and have the attributes of specific Select Agent(s), without being clearly identifiable as SA based on the sequence." To use other words, SynBio opens the door to mixing any toxin from scratch and creating new deadly agents never before seen. As a result, a listing of SAs can never be comprehensive and complete.

Despite this, the NSABB also allowed further SynBio works to proceed with the following argument: "Synthetic biology may be new; but challenges to taxonomic conventional wisdom are not." The NSABB recognized that novel life-forms can evolve into unexpected new life-forms, yet favored allowing further SynBio research to proceed generally unhindered. This is largely because the benefits and positive outcomes from SynBio research have been deemed to greatly outweigh and overwhelm any negatve risks from such research.

A final caution has to do with public health risks and the varieties of biological pathogens that have historically been converted to bioweapons by nefarious persons and states. The Biological and Toxin Weapons Convention cannot regulate, oversee, or steer whatever happens globally in the world of SynBio. Neither can the World Health Organization (WHO). It rests with individual scientists to provide safety and security measures against misuse and abuse of SynBio. Ultimately, synthetic biology means cheaper and widely accessible tools to build bioweapons, virulent pathogens and artificial organisms that could possibly pose grave threats to people and the planet. The danger is not just bioterror but "bio-error"—and mechanisms to prevent both are nonexistent.

Will the Genie Deliver—or Destroy?

Looking at the old paradigm of transgenics, genetic engineering was essentially a cut-and-paste affair in which biotechnologists rearranged pieces of DNA—the self-assembling molecule that instructs living organisms how to carry out every biological process—between already existing species. Today's synthetic biologists can transition from reading genetic code to writing code—to understanding how key pieces of DNA, when combined, sustain life to a point where key pieces can be reassembled to create new and different forms of life. SynBio can create new "genetic networks" and combine those into newer platforms resulting in unique life-forms.

SynBio can now engage in made-to-order life-forms using engineering concepts borrowed from electronics and computing; it can construct simplified versions of bacteria, reprogramming DNA as a computing medium and assembling whole new genetic systems that are entirely human-made. SynBio carries with it the inspirational promise of breakthroughs in medicine, health care, pharmaceuticals, synthetic fuels, and many other products of virtually unlimited benefit and value to future society. In addition, SynBio experts expect to leverage the convergence of nanoscale biology, computing, and engineering toward the creation of new life that transcends the limits of life as we know it. All of this can proceed unfettered and unrestricted as long as the risk dimensions and externalities associated with SynBio are well understood and a risk management system can be emplaced to deal with emerging issues.

Without doubt, widespread debate on the social, economic, and ethical implications of SynBio is needed to sort out the genuine from the mythical so that real risks are plainly understood. The overall benefits of SynBio should not be diminished or dismissed because there is a corresponding risk factor, but instead, strategies are needed to advance SynBio in light of known risks, with due regard for the likely impact of unknown risks that could negate any fruits SynBio conferred.

Nothing should be imposed that thwarts the legitimate onward march of scientific progress and inquiry, which have derived so many benefits to society and will continue to do so. However, a serious discussion must be launched that is not limited to biosecurity issues where we seriously consider, for example, the array of bioweapons/bioterrorism issues and risks that could accrue as well as matters of biosafety (worker safety and environment). More difficult and challenging than developing a national consensus on risk management issues in SynBio, which legitimately extends into agriculture, environment, public health, law enforcement, counterterrorism, proliferation, and military threat arenas, is the question of reconciling the emergence of a global SynBio community where commercial firms, governments, do-it-yourselfers, and criminal terrorists may all have access to the same technology but hold fundamentally divergent aims for its use. Instead, we must converge with pragmatism and expertise, looking at the global array of SynBio endeavors expected to emerge during the 20-year period 2011–31 with an eye toward finding a rational balance between self- and government regulation.

Biological Weapons

Biological warfare, or germ warfare, as it is often called, is the use of biological agents in the form of toxins, bacteria, rickettsia, viruses, or fungi to incapacitate or kill an individual, a specific group of people, or an entire population. Biological warfare may also be used on livestock or crops to affect the food supply and therefore indirectly affect the survival of a population. As a strategic weapon, biological warfare is very effective in posing a credible threat of mass casualties, economic collapse, and the breakdown of society. However, biological warfare is less effective as a tactical weapon, as it may take days or weeks for symptoms of the biological agent to present themselves, and it could be spread to other than its intended victim(s). The longer incubation time for some biological agents makes them ideal as a terrorist weapon, allowing the terrorist to get out of harm's way long before the agent takes effect.

This article expands further on the concept of biological warfare by providing the reader some of the history of biological warfare, the different types and classification of biological warfare agents, indications of a biological attack, and medical management of biological casualties.

The History of Biological Warfare

Biological warfare has been used throughout world history. It has been the weapon of choice by ancient armies to conquer civilizations or assassinate individuals considered enemies of the state.

During the 13th and 14th centuries,the Mongol Empire was one of the most powerful forces on Earth, having conquered most of southeast Asia to eastern Europe. Under the leadership of Genghis Khan, his generals ordered the slaughter of entire populations and the destruction of entire communities to force their enemies to concede to Khan's reign. During one such siege on the city of Kaffa in 1345, the Mongol army was reported to have catapulted the plague-infested bodies of its own troops over the city walls.

In 1763, Fort Pitt, which is now Pittsburgh, Pennsylvania, was under siege by the Delaware Indians in an effort to drive the British out of Ohio. In an attempt to make peace, Captain Simon Ecuyer gave representatives of the Delaware Indians blankets and a handkerchief from a smallpox ward in hope that the tribe would become infected with the disease. Even though some historians believe that the Indians were already infected with smallpox by exposure to soldiers at Fort Pitt and infected settlers, the gift of the infected blankets was an intentional act of biological warfare.

One of the best-known uses of a biological agent as a weapon of assassination took place in 1978. A Bulgarian dissident by the name of Georgi Markov was assassinated by the Bulgarian secret police on the streets of London by injecting a pellet containing ricin into his leg with the tip of a modified umbrella. Ricin is a deadly toxin derived from the castor bean plant.

The most recent use of a biological agent was the 2001 anthrax attacks. One week after the September 11, 2001, terrorist attacks, letters containing anthrax spores were mailed to a number of news media offices and the offices of Senators Tom Daschle and Patrick Leahy. The attack resulted in the death of five people and the infection of 17 others.

Types of Biological Warfare Agents

There are five main types of biological warfare agents: bacteria, rickettsia, viruses, fungi, and toxins. Each of these agents varies widely in its ability to infect humans, its length of incubation, lethality, and effectiveness as a weapon:

- Bacterial agents are single-celled organisms that are the cause of outbreaks of diseases such as anthrax, plague, tularemia, brucellosis, and a number of other diseases.
- Rickettsia are microorganisms that are similar to bacteria but present themselves as parasites that reproduce inside animal cells. These parasites can cause such diseases as typhus, Rocky Mountain spotted fever, or Q fever.
- Viruses are microscopic organisms 100 times smaller than bacteria but unable to grow or reproduce outside living cells. Examples of diseases caused by viruses are smallpox, Venezuelan equine encephalitis (VEE), and viral hemorrhagic fevers, which include Ebola, Rift Valley fever, and yellow fever.
- Fungi can also cause severe diseases in humans, such as valley fever. However, the most effective use of fungi as a biological weapon would be to destroy crops, resulting in widespread hunger and economic disaster. Some examples of fungi that could be used as biological agents include rice rust, cereal rust, and potato blight.
- Toxins are poisons that are produced naturally by living organisms, such as venomous spiders or snakes, or synthetically

extracted from naturally occurring poisons. The most commonly known toxins are botulinum toxin and ricin.

Biological agents can further be classified by their severity and the health risk they pose. The Centers for Disease Control and Prevention classifies these agents in three different categories:

- Category A includes high-priority agents, including those that pose a risk to national security, such as anthrax, botulism, plague, and smallpox. These biological agents are classified as Category A for the following reasons:
    - » Easily disseminated or transmitted from person to person
    - » High mortality rate and could have a major impact on public health
    - » May cause panic and social disruption
    - » Require public health preparedness
- Category B includes the second-highest priority agents such as brucellosis, glanders, ricin, and Q fever. These biological agents are classified as Category B for the following reasons:
    - » Fairly easy to disseminate
    - » Result in moderate morbidity with a low mortality rate
    - » Require extensive diagnostic capabilities and disease surveillance
- Category C is the third-highest category, which includes such agents as hantavirus, yellow fever, and drug-resistant tuberculosis. These biological agents are classified as Category C for the following reasons:
    - » Readily available
    - » Easily produced and disseminated
    - » High mortality rate and major health impact

A National Institute for Occupational Safety and Health crew is suited in full protective gear before entering a simulated biohazard testing area. The exercise was held in early 2012 along with Sandia National Laboratories to test Sandia's Building Restoration Operations Optimization Model (BROOM), a software-based tool to assist in gathering samples following a release of biological warfare agents in public facilities such as airports, transportation centers, and high-traffic public buildings.

Indications of a Biological Attack

Even though it is difficult to detect if a population is under a biological attack due to varying incubation periods or the multiple methods for dissemination, there may be numerous indications of a possible biological attack:

- Appearance of a disease that would not normally occur in that geographic area
- A steadily increasing number of patients showing up at health care facilities with similar symptoms
- The larger numbers of casualties align closely with the wind direction
- Reports from pharmacies on large numbers of specific over-the-counter drugs being sold
- Large numbers of dead animals in an area

Medical Management of Biological Casualties

There are very specific steps to follow in providing effective medical management of biological casualties:

- *Signs and Symptoms:* The victims of a biological attack manifest very specific signs and symptoms depending on the agent used. For example, bubonic plague is characterized by swollen and painful lymph nodes called buboes. Cutaneous anthrax can be identified by black carbuncles and swelling of the victim's skin at the site of infection. Smallpox appears as a rash with the formation of pustules. Because many of these diseases have not been seen for years, it is imperative that medical personnel are trained to recognize the specific signs and symptoms.
- *Diagnosis:* A definitive diagnosis may require some very specific laboratory tests that are not readily available. Therefore, it is important to know which facilities in specific areas have the ability to conduct these diagnostic procedures.
- *Treatment:* Early administration of antibiotics may be critical, depending on the biological agent. For example, antibiotic therapy cannot be delayed more than a day after the onset of symptoms of pneumonic plague. Availability of specific antibiotics, such as ciprofloxacin, may be an issue.
- *Prophylaxis:* Antibiotics may be administered prophylactically for known or suspected exposure. There are also vaccines for such diseases as anthrax and smallpox. However, these vaccines are not readily available to everyone and may require a series of inoculations to be effective.
- *Isolation and Decontamination:* If a disease is readily transmitted from person to person, it is may be possible to isolate the infected to prevent further spread of the disease. Decontamination of surfaces with which the infected have come in contact may prevent further spread of the disease.

Conclusion

This is a brief overview of biological warfare, including some incidents in world history of the use of biological warfare, the different types and classifications of biological warfare agents, indications of a biological attack, and the medical management of biological casualties. This information provides only a baseline for understanding biological warfare. The threat of a terrorist using a biological weapon is a reality. With the advances in medicine and unlocking secrets of the genome, there is a possibility of developing a biological weapon resistant to all medical countermeasures and the ability to target specific populations. Therefore, it is imperative to stay current with the latest information and best practices in preparing for biological warfare.

Blame, Politics of

Human nature seeks to provide meaning behind events, whether they are natural or human in nature. Even most so-called acts of God such as natural disasters could have been prevented or mitigated through better risk assessment and crisis planning. The political blame game is a public process encompassing numerous interdependent actors, including the news media, government legislative bodies and investigatory agencies, public forums, and social media. The rise of the modern mass media has fueled the political pressure to act on public demands for relief, blame, and accountability. Although blame can play a necessary function in moving beyond crisis, negative institutional reactions of defensiveness, avoidance, and the blame game harm a government or organization's reputation and hinder effective crisis management.

Surviving victims and the general public search for answers in the aftermath of a crisis. The assignation of blame gives disasters meaning. Populations live in areas vulnerable to natural disasters or environmental hazards, corporations do not always balance profitability with safety, and technological advances offer greater convenience coupled with greater risk of disastrous failure. The most common questions raised as a result of a crisis situation are the nature of the crisis (what happened and how did it happen) and the reason(s) for the crisis (why did it happen and was it preventable).

If crises are deemed preventable, the next logical question is who was responsible for failing to prevent the crisis. Answering these questions and assigning blame gives disasters meaning. Historical explanations for crises such as natural disasters, crop failures, disease pandemics, or famine often had a religious basis. Blame took the form of magic, sorcery, or witchcraft accusations or God's anger for human failings (the Wrath of God) and calls for repentance and strengthened faith.

In modern times, blame for natural disasters focuses on human factors that failed to prevent, predict, or mitigate such events. For example, those looking to assign blame ask why populations were living in vulnerable areas or why politicians or residents failed to heed scientific warnings. Blame for technological disasters such as chemical or oil spills, bridge or building collapses, or nuclear disasters often centers on operator error.

The assignation of blame in modern times is especially likely when it is determined that a crisis could have been prevented or mitigated and that the necessary measures were known in advance but not acted upon, even if such omissions were involuntary. The need for blame is also heightened in crises that involve loss of life. Scapegoating places undeserved levels of blame on a chosen individual, group, or organization. Psychological motivations for scapegoating include the need to minimize personal responsibility or guilt and the need to maintain a sense of control. Scapegoats are also chosen based on their political convenience.

Information flow has emerged as an especially critical issue in the politics of blame during the mass media era. Avoidance of the media is both more difficult and less effective. The rise of social and electronic media such as Facebook, YouTube, and Twitter has increased the speed and scope of crisis reporting. Vivid images of damage and struggling victims increase the political pressure to act on public demands for relief, blame, and accountability. Media coverage also fuels the public blame game through sensationalism, misreporting, and bias toward the coverage of conflicts such as the blame game that drive the viewer interest necessary for higher ratings. On the positive side, governments and organizations utilize the media to quickly disseminate information on proactive crisis response and problem-solving actions that can reduce the negative aspects of the political blame game.

Political Uses of Blame and Their Effects

Blame for poor crisis management is used in the promotion of political agendas, including increased or reduced government spending, size, and regulatory or disaster relief roles and calls for increased self-reliance and reduced dependency on government assistance. Excessive planning, bureaucracy, and paperwork requirements ("red tape") are frequently blamed causes of governmental crisis response inefficiencies and delays. Statistical correlations between election years and rises in disaster declarations and allocation of relief funds are another example of the political nature of crisis management.

Blame for crises or failed crisis management is also a common political tool, one which often encompasses historical revisionism or distortion of the facts. Politicians and their constituents tend to be more focused on immediate concerns such as economic development, job creation, budget cuts, or deficit reductions. Precrisis planning and mitigation are often either neglected or pushed to the back burner. Other issues that affect precrisis preparation include either too little or too much planning, lack of coordination between government agencies and levels of government, funding shortfalls, the misuse of allocated funds, lack of political will, poor leadership, and lack of innovation.

The commonly held political belief that governments are obligated to protect their citizenry from internal and external threats is another important aspect underlying the politics of blame. Many observers believe that individual citizens have become less prepared for crisis because of increased reliance on government aid. Blame is then placed on government agencies or officials when that aid is absent or slow to arrive. Nongovernmental organizations (NGOs) such as voluntary, religious, or business organizations usually provide faster crisis relief and recovery aid, as they are less constrained by bureaucracy and have fewer or no paperwork requirements ("red tape") for aid recipients. NGOs, however, are not immune from the politics of blame and its effects on crisis management.

The U.S. government response to Hurricane Katrina and its impact on the U.S. Gulf Coast and New Orleans is held as a leading example of the politics of blame. The modern politicization of disaster relief in the United States began in the second half of the 20th century. Individual citizens had begun to look to the federal government for aid on a large scale during the Great Depression of the 1930s under the Franklin D. Roosevelt administration's New Deal programs. Previously, most crisis relief had come from local, state, or private organizations. The Dwight D. Eisenhower administration was the first granted the authority to make a presidential declaration of disaster areas eligible for federal aid. The federal aid process was further institutionalized and politicized under the Jimmy Carter administration with the formation of the Federal Emergency Management Agency (FEMA) in 1979.

In the aftermath of Hurricane Katrina, sensationalized reports of widespread looting, violence, and rape slowed rescue and relief efforts, as military and law enforcement personnel were either diverted or cautious to enter reputedly dangerous areas. Many of these reports were later proved false. FEMA response was delayed by lack of coordination with state and local authorities, lack of sufficient or accurate information, and excessive bureaucratic requirements for aid dispersal.

The same political issues that contribute to poor crisis management and fuel the blame game also operate within the international aid community. Many developing nations and failed states lack sufficient resources or infrastructure for effective crisis management while housing vulnerable populations. Political motivations for international crisis relief include potential national security impacts of overseas crises and the preservation of international goodwill. Developed nations and crisis relief organizations have received blame for perceived slowness of response, sending aid unwanted by the stricken country's government or with strings attached, ignoring crises such as ethnic cleansing or famine until they become overwhelming, focusing on crisis response instead of mitigation and planning, and inadequate funding, especially for long-term recovery.

Negative Consequences of the Rush to Blame

The rush to assign blame and the organizational responses that drive that rush often have negative consequences for both the organization and the people affected by the crisis. Some governmental and organizational crisis management strategies tend to exacerbate blame. Counterproductive organizational responses to crises that play a critical role in the politics of blame are found across the globe and within all types of organizations. Organizations often adopt a defensive mentality in a crisis situation, which can fuel the desire to avoid media scrutiny and public blame or to place blame elsewhere. A defensive stance may also enhance the perception of justifying rather than honestly analyzing the organization's role in the crisis while giving the public appearance of avoidance of organizational responsibility and insensitivity to those affected by the crisis.

Many organizations seek to avoid media contact while internally handling crisis situations, but such an approach can have unintended negative consequences. Misinformation and omissions, whether accidental or intentional, are likely to be pursued within the professional or social media, resulting in negative publicity. The blame game is also fueled by the inclusion of assumptions, honest misinformation or overly optimistic or pessimistic statements, or outright lies within an organization's information flow during or after a crisis.

Blame that centers on a particular scapegoat ignores the complexity that underlies the chain of events leading to a crisis situation. The blame game also deflects attention away from needed crisis relief and recovery efforts, which is especially harmful in the immediate aftermath of a crisis when timely response is of the essence. Finally, the assignation of blame diverts resources from the accurate identification and correction of the causes of the crisis, and shifts organizational, media, and public focus away from organizational solutions to the crisis, mitigation of its effects, and prevention of similar future crises.

The politics of blame has a strong influence on government crisis management operations, especially within the public sector. Government agencies must manage public expectations that they will actively respond to blame assessments through open, thorough investigation, identification of responsible parties and causal factors, and remedial action. In their rush to recover political goodwill after blame, many governments and organizations tend to rush to disperse crisis relief funds without first establishing an adequate process for the prevention of wasteful or fraudulent use. In the long term, the avoidance or deference of blame often harms an organization's public reputation.

Organizations that maintain awareness of the tendency of these exacerbating behaviors can remain on guard against them, thus minimizing the development of the so-called blame game. There are also a number of factors that mitigate the negative impacts of the blame game. Open, honest acknowledgment of the crisis, its effects, and any individual or organizational responsibility as well as mitigation actions will help alleviate the public desire for scapegoating or blame assignation. A focus on immediate relief and recovery will maintain public and political goodwill while allowing the truth to come out in the later long-term postcrisis assessment process. The process of blame and punitive measures then allows a government or organization to recover from crisis, resume normal operations, and recapture public confidence. Often the individuals targeted as scapegoats are then reassigned, fired, or otherwise removed from their precrisis roles. Such proactive measures are helpful even for those organizations that truly believe they are not or are only partially responsible for a crisis situation or those organizations that wish to avoid open statements of culpability that may make them vulnerable to future litigation. Awareness of the political and emotional nature of crisis situations reduces the negative impacts of the human tendency to blame.

Blizzards

A blizzard is a winter storm that has strong winds, significant wind chill, and poor visibility due to blowing snow. The Meteorological Service of Canada uses the following general criteria for issuing blizzard warnings: strong winds reaching 25 mi/h (40 km/h) or greater, visibility of less than 0.6 mi (1 km); cold temperatures; and conditions lasting in duration at least four hours. Blizzards, which can last for days, can create a variety of dangerous conditions. Heavy snowfall and whiteout conditions can make travel difficult to impossible. In whiteout conditions people have become lost even when going only short distances. Exposure to low wind chill caused by strong winds and cold temperatures can result in frostbite and/or hypothermia, both of which pose risks to health and safety. Blizzards are also known to cause power outages, falling trees and branches due to high winds and/or accumulation of heavy snow, frozen water pipes due to the cold temperatures, and flooding from melting snow. Extreme weather events are on the rise, with an increase in frequency and duration attributed to climate change.

Cold temperatures and the presence of ice and snow make winter in many countries a naturally hazardous season. Winter weather conditions can quickly become dangerous, often with little or no warning. Environment Canada issues a variety of severe winter weather watches and warnings to alert the public about the approach of hazardous winter conditions. Winter storms and excessive cold claim over 100 lives each year in Canada. In Canada, blizzards occur most often in the southern prairies, the Atlantic region, and the eastern Arctic. Personal preparedness measures can be undertaken by learning more about the different kinds of winter hazards and how to plan ahead for possible emergencies. Government environmental and weather agencies issue alerts when severe winter weather is on the way and provide information on the causes, characteristics, and potential effects of various winter hazards, including blizzards.

One of the worst blizzards in American history is widely known as the Great Blizzard of 1888. The blizzard brought 40–55 inches of snow to the northeast coast. Along with the heavy snow came snow drifts as high as 50 feet and 45-mile-per-hour winds. Many people were trapped in their homes for weeks because of the weather conditions and the inaccessibility of the railroads. In addition to the trains, telegraph lines, water mains, and gas lines were also located above ground. It is estimated that the storm resulted in over 400 deaths and many more injuries. Thousands of wild and farm animals froze to death in the blizzard. In the wake of the storm, officials realized the dangers of above-ground telegraph, water, and gas lines and moved them below ground. In New York City, a similar determination was made about the trains, and within 10 years, construction began on an underground subway system that is still in use today. With hindsight, there are many instances where poor judgment led to death or injury from blizzards.

Individuals are cautioned not to venture out in a blizzard. If people must go outside, they should dress properly to stay warm, wearing thin layers of loose-fitting clothing to trap body heat and promote air circulation. Outer clothing should be tightly woven, hooded, and water repellent. Because most body heat is lost through the head, people should always wear a hat when it is cold outside. If it is extremely cold, one should cover the mouth and exposed skin with a scarf, neck tube, or face mask and pay particular attention to the wind chill index, which can create dangerously cold conditions. People should be on alert for signs of frostbite by checking for numbness or white areas on the face and extremities (ears, nose, cheeks, hands, and feet, in particular). One should get medical assistance immediately if there are any signs of confusion, slurred speech, stiff muscles, or uncontrollable shivering. These are all symptoms of a potentially fatal condition called hypothermia, which occurs when the body loses heat faster than it can generate it.

Depending on the amount of snowfall, travel can be hampered and highways can be closed. The Canadian Automobile Association advises drivers to slow down when driving on snow-covered roads and leave plenty of distance between vehicles. Winter tires provide traction, which is essential for turning and stopping on wet, slushy, or icy surfaces in colder weather. Windshield washer fluid is necessary in the reservoir with a rating in the minus 40 degrees C temperature range. When driving in bad weather, think caution, plan ahead, and make sure there is enough fuel by keeping the fuel tank at least half full. An emergency car kit should always be stored in the vehicle. The basic emergency kit for cars should include the following items: food; water; blanket; extra clothing and shoes; first aid kit; small shovel, scraper, and snowbrush; candle in a deep can and matches; crank flashlight; whistle; road maps; and a copy of an emergency plan. Additional items that can be kept inside the trunk include sand and/or salt; antifreeze/windshield washer fluid; tow rope; jumper cables; fire extinguisher; and a warning light or road flares.

If people must travel during a blizzard, they should do so during the day and let someone know the driving route and anticipated arrival time. If the vehicle gets stuck in a blizzard or snowstorm, remain calm and stay in the car. Allow fresh air into the vehicle by opening the window slightly on the sheltered side, away from the wind. It is possible to run the engine about 10 minutes every half hour if the exhaust system is working well. Beware of exhaust fumes and check the exhaust pipe periodically to make sure it is not blocked with snow. Remember that potentially fatal carbon monoxide fumes have no smell. To keep hands and feet warm, exercise them periodically. In general, it is a good idea to keep moving to avoid falling asleep. Having a storm readiness plan in place saves valuable time if severe weather such as a blizzard strikes.

Border Disputes

Border disputes involve situations where a certain piece of territory bordered by more than one nation is claimed by two or more of these nations. Some border disputes take place in isolated areas, where the precise boundary between two nations is uncertain, while others involve a long-standing disagreement regarding the territorial limits of two states. Although certain border disputes arise suddenly, others recur over time and with some regularity. In either case, nations, corporations, organizations, and individuals that rely upon a border being open are best served through having a crisis management plan that deals with a contingency plan in the event of a border dispute.

Background

Borders are the geographic boundaries of nations or other political entities such as states, counties, and municipalities. Some borders are natural, such as geographic attributes that present natural obstacles to entry and egress; examples include oceans, lakes, rivers, forests, mountains, and the like. Other borders are political, separating two nations because of an agreed-upon division of territory, reached as the result of tradition, war, or negotiation. Examples of political borders include the United States–Canada border and the Great Wall of China. The state of diplomatic relations between two nations sharing a border often affects the types of controls in place at checkpoints and in other areas.

The presence of a border affects an area in economic, political, and other ways. Historically, taxes imposed on goods brought across a border have constituted a major, if not primary, source of revenue for governments. The proximity of two or more jurisdictions also creates special opportunities that favor border trade. Different taxes imposed on certain goods on different sides of a border make it advantageous for consumers to purchase those goods on one side of the border to avoid these taxes. Different policies related to a variety of other services, goods, and programs also may cause individuals to travel to one side of the border or the other to obtain these. Services, goods, and programs that often differ by jurisdiction include the provision of abortion, alcohol, medical care, narcotics, pornography, prostitution, and the like. Although border disputes often involve disagreements regarding territory on land, such quarrels may also involve maritime matters.

Many positive benefits result from cross-border interactions. Residents of one nation often travel from their homes on one side of the border to their job on the other side of the border. Certain regions, such as Europe, have devised means like the European Union to minimize the disruption borders place on their residents. Conversely, the closing of borders, such as the Blue Line between Israel and Lebanon, can greatly diminish trade and other interactions between individuals who live on opposite sides of the border. Political disagreements or disputes often result in the closing of borders. Even when borders are not closed, many nations establish checkpoints where border control agents can inspect those who wish to cross from one side of the border to the other. Although some areas of the globe have worked to reduce border control, other areas, such as the United States, have increased border security since the 1990s. Incidents or events that close borders cause less disruption if a crisis management plan is in place to assist in such an event.

Planning for Border Disputes

Border disputes that are not managed well can have catastrophic results for individuals living in the border region as well as for the nations involved in the disagreement. For example, in 1978 a group of Palestine Liberation Organization (PLO) operatives initiated the hijacking of an Israeli bus that led to the death of 38 Israeli citizens, including 13 children. Three days after the slaughter, the Israeli army launched Operation Litani, an invasion of the border region of southern Lebanon where PLO bases were located. The Israeli action resulted in the death of more than 1,100 individuals, mostly Lebanese and Palestinian civilians. After Operation Litani ended, the Israelis continued to skirmish with the PLO and other Lebanese factions. By 1985 these conflicts had proven costly to both sides, with many civilians, including women and children, killed as a result of bombings and other attacks launched from southern Lebanon. To meet this challenge, the Israeli Defense Force (IDF) invaded a slim borderland buffer zone in 1985. This buffer zone, known as the Israeli Security Zone, was maintained by the IDF until 2000. The Israeli Security Zone was kept free of weapons or other forces other than those of the IDF. The Israeli Security Zone was intended to prevent mortar fire and other small arms from harming Israeli border towns. As a result of this occupation, however, cross-border traffic was halted and economic harm came to those who had depended on trade between the two nations. Such devastating results spur many government entities to seek alternatives to border disputes that will be less costly and disruptive.

As a means of protecting against border disputes, many nations allocate resources that are used to defend and police their borders. A nation may use its armed forces, civilian police forces, and civil service employees, as well as combinations of these bodies, to maintain order and enforce the law. In the United States, for example, borders are controlled by Customs and Border Protection (CBP). The CBP is an agency of the U.S. Department of Homeland Security and is responsible for enforcing hundreds of statutes and regulations. Created as a result of the decision to merge the U.S. Customs Service and the Immigration and Naturalization Service (INS) as part of a general reorganization of security forces after the 9/11 attacks, the CBP is responsible for three overarching matters: trade, travel, and border security. With regard to trade, the CBP is accountable for ensuring that goods arriving in the United States have the appropriate fees and duties paid to the U.S. government. The CBP also works to ensure that U.S. trade is secure from threats of terrorism, both around the globe and at the borders. For travel, the CBP works to maintain the United States' reputation as a welcoming country while also efficiently processing over 300 million visitors who cross its borders each year. Finally, with respect to border security, the CBP represents the largest law enforcement agency in the United States. This group works to secure the nation while coordinating trade and travel.

Border disputes can disrupt the political and economic well-being of an area. For most residents of an area near a border, cross-border trade and easy entry and egress are seen as great benefits. For that reason, macro regional integration initiatives, such as the North American Free Trade Agreement (NAFTA) and the European Union (EU), are embraced as helping establish cross-border regions that are more resistant to unilateral actions. Such organizations have a twofold effect on border disputes. First, macro regional integration initiatives build support for cross-border integration by creating regional interest in the continuance of cross-border relationships. Increases in intercultural communication and dialogue are augmented by mutual or common financial interests that make serious border disputes less likely. Second, the agreements that establish macro regional integration zones often contain arbitration or other judicial procedures to adjudicate disputes among nations. These avenues assist in achieving a resolution to disputes that stops short of closing down border traffic. Entering into treaties and other agreements with neighboring nations is thus a strong preventive step that guards against crises that may develop as a result of border disputes.

Despite these carefully laid precautions, border disputes still occur, both on land and at sea. Indeed, as schools of certain fish become scarcer and the possibility of harvesting underwater resources becomes more likely, interest in territorial rights to certain sea locations has increased. The governments of the People's Republic of China, the Philippines, and Taiwan, for example, all assert sovereignty over Scarborough Shoal, a group of very small islands and reefs in an atoll shape located in the South China Sea. Although the Scarborough Shoal is uninhabited, antagonism between the three nations, and especially China and the Philippines, continues, and initiatives to resolve territorial disagreements also continue. In 2011, for instance, China and Japan engaged in a series of talks designed to diminish hostilities between the two nations over control of certain maritime areas. The Chinese and Japanese have found that including greater numbers of constituencies in the talks has made it more possible to reach consensus on certain hot topics, such as natural gas exploration and fishing rights. The inclusion of business interests, coastal residents, administrative agencies, and others, in addition to diplomats, made discussions focus on the consequences to the region. If this success continues, other border disputes may well include individuals who represent multiple perspectives.

Bounded Rationality

A discussion of bounded rationality must include a review of two definitions: What is meant by the term *bounded*, and what is meant by the term *rationality*? Limited, circumscribed, finite, and restricted are defining words that suggest parameters of a bounded state or condition. The term *rational* denotes a quality or state of reasonableness, or a sensible, logical, or well-founded condition. The origins of the concept of bounded rationality are historically rooted in commonsense approaches to the art and practice of decision making. The concept has practical relevance to a variety of disciplines: crisis management, crisis negotiation, crisis communication, crisis planning, mediation services, industrial planning, governmental policy making, economics, and individual decision making, to name a few.

Human Limitations for Rationality

The scientific community in the 18th and 19th centuries recognized human limitations that had long been understood but inadequately defined. They recognized that human intelligence had finite capacities or limitations; that the then-current state-of-the-art construction, engineering, and instrumentation technologies were often woefully inadequate to the tasks of producing accurate measurements intended to shed light on phenomena in nature and the constructed world; and that the prevailing theories and observations related to the emerging medical sciences were based on incomplete intelligence or a lack of vital information to make reasonable, if not optimal, diagnoses or decisions.

As late as the Renaissance, European physicians relied on human anatomical information that dated back to the time of Galen, the pioneering Arabic physician of the 2nd century C.E. Galen's anatomical descriptions filled a large gap in medical knowledge, but even Galen's contributions fell short of fully accurate identification of the human skeleton. Anton van Leeuwenhoek, a Dutch lens maker who lived from 1632 to 1723, developed lenses that produced a dramatic 200 percent magnification of what he identified as "animalcules" or single-cell life-forms. The improved lenses led to development of the scientific microscope, which enhanced scientific theorizing and the discovery of bacteria, but it would still take another two centuries for the scientific community to produce lens instrumentation powerful enough to view living viruses. Diagnosis and treatment decisions related to viruses required information that could not exist until visual confirmation of viral life-forms could be confirmed. Medical science remained in a bounded or circumscribed state.

The term *rationality* derived from the Latin and adopted French word *ratio*, defined as a lack of information or intelligence, or more specifically, indicating a finite or incomplete intelligence. In the 20th century, Herbert A. Simon refined this informal concept, pointing out that for rational decision making to occur, cognitive limitations, the extent to which individuals are bounded by lack of adequate information, lack of intellectual capacity, and available technical and computational capacity needed to be taken into account in order to make reasonable decisions. Simon argued that a rational action implied behaving in a manner appropriate to a particular situation—to the specific context in which a decision is made. Emotional factors such as fear must be considered as influences that bind or restrict the development of an optimal decision. Physiological and psychological limitations associated with fear, stress, and the fight or flight syndrome, as described in the general adaptation syndrome developed by Hans Selye, constitute factors that may contribute to less than rational or reasonable decision making. The psychological effects of very high levels of stress are well established. The human capacity for sustained attention or the ability to concentrate is diminished, and how an individual perceives what is required for optimal decision making can become altered by real or even imagined crisis situations. What will satisfy immediate or near-term safety or survival may reduce thinking processes to acting upon and accepting a very limited range of what Simon called "satisficing" or satisfactory decisions.

Influences of Locality on Decision Making

A factor that may limit the selection of an optimal decision is a decision maker's regional or local geographical setting. Individuals and groups are influenced by their physical and cultural environments. Planners and decision makers who have long resided in desert climates may contribute prejudiced policy recommendations on planning for hurricane preparations. Regardless of how much we are convinced that our recommendations are detached and objective, we may tend to generate less than optimal decisions.

This very human problem of restrictions on our cognitive processes is described as "local rationality." The problem is not an immediate concern to populations that are not at significant or immediate risk. From a crisis management perspective, governmental agencies are frequently confronted with potential environmental or safety policy decisions that result in public opposition, often referred to as NIMBY or "not in my backyard" issues.

Local rationality has significantly influenced national governmental decisions on where and how to safeguard or dispose of weapons-grade chemical and radioactive waste that will pose serious threats to human health for thousands of years. Billions of U.S. tax dollars were spent on selecting, excavating, and preparing a remote site in the state of Nevada (Yucca Mountain) to house such waste for thousands of years or until advanced waste remediation technologies could be safely employed to reduce risks of radiation exposure.

Despite the fact that Yucca Mountain was ready to accept waste, the site was never opened. Fear of future radiation exposure in the large Las Vegas urban area was a critical factor in halting the opening of the Yucca Mountain site.

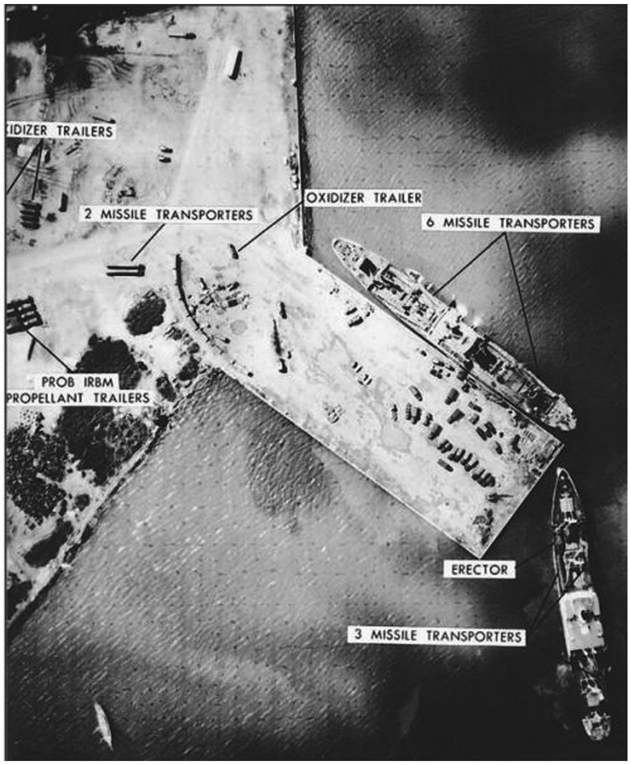
Time- and Cost-Bound Influences

Reasoned or rational decision-making processes should include realistic outcomes that would produce a beneficial outcome, and the decision-making process would factor in cognitive and organizational constraints that might result in a weaker decision. Decision planning guided by these constraints is understood to be adaptive or conducted within rationally bounded guidelines or parameters. Daniel Hahnemann and Amos Tversky found that decision processes occur within time- and cost-bound realities, and even when optimal technologies and expertise are available to decision makers, the optimal decision may not be made. Planners often arrive at "satisficing" or acceptable decisions.

An optimal decision would require planners to possess all the currently available and appropriate information vital to informing a decision. All known alternative decisions would also need to be factored into selecting a decision. Influencing factors such as cost-benefit analysis of each alternative would need to be evaluated to determine the action that would result in the safest, healthiest, most fiscally cost-efficient, most timely, and most appropriate decision.

The Influence of Personal Views

Decision analysts report that results may not be predicted with a high degree of certitude. Important decisions involving the safety or security of communities and nations are fraught with elements of human emotion and personal agendas that may not be readily apparent even in the most organized and objective planning processes. In the United States, a large percentage of the population view driving an automobile as a basic right. Governmental efforts to develop high-speed and light-urban rail transport have met with mixed results, and public opinion and automobile-related businesses and industrial interests have long campaigned against these forms of transportation. Yet, with each significant spike in gasoline prices, American drivers have increasingly turned to available rail and bus transport to save money. It is evident that emotion, cost, time, and availability are critical factors in the bounded



This 1962 U.S. Department of Defense photo shows Soviet missile equipment being loaded at a port in Cuba. The Cold War's tense Soviet–American relations came to a head in October 1962 during the Cuban Missile Crisis.

rationality equation when an individual chooses to drive or take a bus or train to work or to market, providing that alternative forms of transport are actually available. It is important to recognize that transport planners are also members of the public, and their own deeply held views on the rights or abuses of the personal automobile are factored into policy planning regardless of how much effort is put into detaching emotional and personal inputs.

Alternative Decision Possibilities

Developing alternative decision options is essential, particularly when efforts to reach an agreement reach an impasse. The 1962 Cuban Missile Crisis between the former Soviet Union and the United States provides a case in point. After tense communications between President John F. Kennedy and Soviet Premier Nikita Khrushchev, the United States decided to halt a naval blockade of the island nation of Cuba, where the Soviet Union had constructed missile silos and awaited Soviet fleet shipments of nuclear weapons. The Kennedy administration committed to withdrawing nuclear weapons from Turkey, a country that bordered the former Soviet Union, if the Soviet Union would withdraw missile shipments. The Soviet Union returned the nuclear missile cargoes to Russian ports. Both governments saved face, as the two superpowers backed away from the brink of a possible nuclear war.

The Kennedy administration reviewed numerous alternatives in seeking to resolve one of the gravest political and military crises since the end of World War II. Both leaders and their governments were bounded or constrained by political and military agendas. The decision-making process was time-bound in a dangerous face-off as Soviet cargo ships neared the U.S. blockade. Both governments arrived at what could best be described as a rational decision. They averted a catastrophe of global proportions and crafted a decision based on reason.

Adaptive Optimizing Decision Making

Bruce Bueno de Mesquita informs planners that they should approach the decision-making process in an "adaptive" manner, always adapting to be flexible to changes and limitations of the specific environment in which their decision planning takes place. However, decision makers must recognize that their organizational culture may not allow for decisions that are in opposition to their stated program planning mission and goals. Regardless of time restrictions, environmental conditions, cost, and idiosyncratic constraints, decision planners must establish protocols that seek an optimal decision among the alternatives considered.

Brain Drain

The term *brain drain* refers to the migration of skilled workers and their families to other countries or regions. Human capital flight is primarily from developing countries to industrialized or oil-rich countries, but its effects are also a concern in some industrialized countries. Brain drain can be long term, such as decades of emigration from African nations, or form a rapid crisis such as the emigration from East Germany to West Germany between 1945 and 1961 in which 20 percent of the population, mostly skilled, resettled.

Social Factors Driving Brain Drain

Brain drain is driven by demand for skilled labor. Underlying social factors that motivate brain drain include poverty, economic depression, low pay, currency devaluation, crisis and conflict, political chaos and corruption, crime, falling educational standards, inadequate infrastructure, services and health care, and environmental collapse. Host countries attract skilled workers with their robust economic outlook, higher salaries, quality schools, strong infrastructure and services, and social stability and mobility. Sixty percent of world migrants move to developed countries; the remainder is between developed countries. There is limited migration from developed countries to developing ones. Ninety percent of highly skilled migrants live in the nations of the Organization for Economic Co-operation and Development; of this population, 85 percent live in the United States, Canada, Australia, the United Kingdom (UK), Germany, and France. Seventy percent of temporary migrants in the United States are highly skilled, whereas they form only 40 percent in the UK and Canada and 15–30 percent in France.

This asymmetrical skill flow is attributed to the lower linguistic adjustment required of migrants moving into countries where the lingua franca English is spoken. Brain drain severely impacts sub-Saharan Africa, Caribbean islands, India, China, Vietnam, Pakistan, Indonesia, and former Soviet states. Key industries damaged by brain drain include health and medicine, business services, banking and finance, computers and information technology, and industrial high tech. Between 1990 and 2000, international migration expanded by 14 percent, and the result was an increase from 154 million to 175 million people living in host nations. The brain drain is more extensive today than two decades ago because skill-selective immigration policies in Australia, New Zealand, Canada, and the United States attract the top workers.

Crisis and Political Influence

Crises or major political shifts encourage brain drain. For example, due to political upheaval between 1989 and 1997, 233,000 South Africans permanently emigrated to the UK, the United States, Canada, Australia, and New Zealand. Due to economic and environmental problems, 80 percent of skilled workers have left the small Caribbean-basin countries of Guyana, Jamaica, Haiti, Grenada, and St. Vincent and the Grenadines, producing one of the most brain-drained regions in the world.

Migration is motivated by the income differential between developing and industrialized countries. Nigerian medical schools and hospitals have lost many of the most talented practitioners because they receive far better salaries in countries like Saudi Arabia. Working conditions and equipment in developing countries are often inadequate, leaving human talent and potential underutilized. Engineers, scientists, and researchers from India, China, and Korea have moved to countries like the United States in great numbers to take advantage of better pay, benefits, and living conditions. Migration networks form and stimulate community migration; a sequential migration chain emerges, with settled migrants housing new arrivals. Generalized reciprocity supports migrants until they are self-sufficient.

Positive Outcomes

Positive effects of migration include an overall improvement in migrant child health outcomes, lower infant mortality, and greater birth weights; however, migrant infants were less likely to be breast-fed and vaccinated. Feedback effects like money remittances stimulate migration, and they represent an important source of income in many developing nations. Remittances form the largest external input on the economy of Haiti, for example. However, most benefits from migration are internalized in the host nation, and money remittances only trickle back. Money remittances are usually spent on consumer goods and not placed in productive investments that act as multipliers. Return migration of individuals with new skills represents potential gains. The establishment of business networks in source and host nations can stimulate trade and the flow of knowledge. Overall, however, the negative effects of brain drain exceed the positive aspects of “brain gain” when one considers how the acquisition of language skills slows the productivity of the newly arrived, especially in non–lingua franca host countries. Plus, many skilled migrants are hired to do menial work for which they are overqualified, resulting in “brain waste.” Incomes for brain waste jobs are lower, and educational assets are left fallow.

Negative Outcomes

The brain drain has negative impacts in source countries. Economic costs include government spending on training individuals who migrate with skills acquired at taxpayer expense. Middle- and low-income countries are left with a smaller number of workers possessing a tertiary education compared to high-income countries. The loss of creative and entrepreneurial professionals slows job creation and impedes efficiency. When parents emigrate and leave their children behind, the children’s educational attainment is lower. Brain drain also diverts attention away from domestic problems and investment because professionals orient their skills and resources to other nations. The departure of skilled professionals results in the loss of international recognition in institutions, the overworking of those who remain, the use of under- or less-qualified replacement workers, weaker modeling in the workplace, and the erosion of morale in postgraduate education, and, in the context of health care, has negative implications for the health of the citizenry. The brain drain results in the loss of present and future savings, collected taxes, taxpayer investment in education, and sources of leadership.

Mitigation of Brain Drain

Various methods can mitigate the stresses caused by brain drain. Governments may increase the net incomes of the highly skilled and decrease the redistributive taxation that operates at their expense. If governments want to keep the highly skilled and the system of redistributive taxation, education and public discourse need to persuade citizens that taxation is beneficial for the common good. Proactive policies that recruit skilled foreigners can help turn brain drain into brain gain. While it may be desirable to offset brain drain losses with open immigration policies, in many states this incites nationalist anti-immigration sentiments. Government bureaus that only handle skilled personnel may offset this hostility.

Host countries can support education in source countries with money and expertise in critical areas so that individuals need not settle abroad for education. Source enterprises can upgrade human resources by offering training. Host and source countries can also require temporary migration with circulation back to the source country. Governments can produce more high-skills graduates and improve living conditions through security and economic opportunity. As women have lower migration potential than men, affirmative action on the basis of gender may be considered. Placing limits on the amount of currency that can be taken out of a country may also diminish the attractiveness of migrating.

Strengthening loyalty can be accomplished by cultivating community bonds and breaking the culture of anonymity so that there is an emotional cost to emigration. Citizens will stay if they are proud of their nation's political, legal, economic, educational, and social institutions. Another policy that may slow brain drain outside the Anglophone world is the affirmation of linguistic territoriality wherein the national language is prioritized over the English lingua franca. Governments can assert the dominance of the territorial languages throughout public education. Host governments can impose compulsory education in the national language and culture to encourage assimilation.

Corruption, nepotism, and the lack of accountability need to diminish just as law, order, meritocracy, and justice need to increase in the source country. To stem the loss of health care professionals in developing countries, providers need to be better remunerated, restrictions on private practice lifted, a stable currency exchange rate adopted, interest rates on loans regulated downward, budgetary allocations for health care increased, and more scientific research projects funded; medical education should shift its emphasis from curative to preventative medicine to increase regional relevance and decrease advantages on the international market. The government can also regulate professionals who seek international opportunities in order to negotiate the migrant's length of stay abroad, and temporary or permanent returnees should be encouraged to share their skills and knowledge.

Bridges

Bridges are essential engineered and constructed structures that support elevated roadways for transporting vehicles, trains, and foot traffic over waterways, roads, valleys, and transportation obstacles such as cities and railway yards. The safety of bridges is often taken for granted by the public, and bridge failures that result in mass casualties have been rare until the last decade. Bridges in many parts of the world are aging and have outlived their engineered life spans and need to be replaced or retrofitted. Thousands of obsolete bridges remain in use. Obsolete bridges are often structures that were constructed over a century ago; they may not be unstable but they are not capable of sustaining the weight loads of today's vehicles, nor can they provide the multiple lanes needed to support the increasing volume of traffic. Bridges also provide terrorists with targets of opportunity.

Recent Bridge Engineering Research Findings

In 2009, the American Society of Civil Engineers (ASCE) issued findings on the safety of critical infrastructure in the United States. The study assigned letter grades on the safety of dams, highways, levees, sewers, and bridges. On a graded scale of "A "to "F," bridges received a grade of "C" due to the high number of unsafe bridge findings. The report found that 26 percent of U.S. bridges were structurally deficient. For a bridge to designated as structurally deficient, it must have a defect significant enough to require posted weight load limits, speed restrictions, and signage warning of flood dangers in locations where flooding regularly occurs. Internationally, bridge safety was evaluated in a 2009 technology study that identified bridge strikes, where bridges are struck by objects such as barges, boats, and locomotives. Large-object strikes accounted for a high number of bridge failures in the United States and Europe but accounted for few collapses in other parts of the world, often due to underreporting. Bridges carrying overloaded vehicles and trains were identified as the most frequent factor contributing to bridge failures. Although the 2007 Minneapolis bridge collapse involved multiple causes, overload was determined to be a contributing factor. Increased weight loads and increased numbers of vehicles on the road have put unmanageable strains on aging bridges.

Bridges in the United States and Canada are engineered for safety and serviceability for a period of approximately 50 years. A large number of them are at least 43 years old and approaching the need for replacement. Of 600,000-plus U.S. bridges, 12 percent were found to be structurally deficient in 2008, and almost 15 percent were described as functionally obsolete. In rural areas, 25 percent of bridges were deemed to be structurally inadequate, as well as 30 percent of urban bridges. Motor freight traffic has increased by nearly 50 percent in the last 20 years, and urban areas account for the largest share of traffic in the United States, indicating that urban area bridge safety is a critical public safety concern. Bridges that are in the process of being constructed account for the second most frequent cause of collapses worldwide.

Bridge Protection Against Terrorist Attack

A commission comprising governmental, engineering, scientific, and security experts convened in the United States reported that nearly 1,000 of the 600,000-plus bridges in the United States were vulnerable to terrorist attack. The commission called for risk assessment evaluations of bridges, enhanced security measures, and structural retrofitting to diminish the potential for terrorist activities. As recently as May 1, 2012, five men describing themselves as anarchists were arrested planning to blow up an urban, highly trafficked bridge in Cleveland, Ohio. Worldwide, in May

Case Study: Recent Bridge Crises

The highly trafficked Interstate 35 West Bridge spanning the Mississippi River between the U.S. cities of Minneapolis and St. Paul, Minnesota, collapsed during the evening rush hour on August 1, 2007. The Interstate 35 bridge failure brought about reviews of bridge structural integrity and safety around the industrialized world. The catastrophe resulted in 145 reported injuries and 13 fatalities.

In western Europe, on March 5, 2011, a bridge constructed in 1885 linking the Portuguese communities of Catelo de Paiva and Penafiel collapsed, resulting in the fatalities of a busload of 60 passengers and 10 people crossing the bridge in personal and commercial vehicles. The 1885 bridge was determined to be obsolete and not designed for today's significantly increased volume of traffic, larger vehicle sizes and weight loads, and speed capabilities of modern vehicles.

In Asia, bridge failures have become a recurrent safety problem. In the People's Republic of China during July 2011, three bridges collapsed, reportedly due to incorrect proportions of sand mixed with concrete used to construct the bridges. In one of the failed bridges, trucks had been prohibited by law from crossing the bridge due to their heavy loads that caused bridge destabilization. Police video surveillance cameras revealed that late-night truck crossings were responsible for destabilization of the bridge and contributed to its subsequent collapse. Over 1,000 trucks were identified making unauthorized crossings, often carrying loads of more than 100 tons.

2012 three completed terrorist attacks on bridges resulted in explosives detonated in Myanmar and India, and one bomb scare occurred in Kenya.

BS 25999

BS 25999 is an internationally recognized business continuity management (BCM) standard developed in 2006 by the British Standards Institution (BSI) in consultation with the UK business community, replacing the Publicly Available Specification 56 (PAS 56) issued on the same subject in 2003. The standard provides a basis for understanding, developing, and implementing business continuity plans within an organization and a comprehensive set of requirements based on BCM best practice covering the whole BCM life cycle. The requirements in the standard are generic and are intended to be applicable to all organizations, regardless of type, size, and nature of business. The standard is divided in two parts: BS 25999-1 and BS25999-2.

Since June 2010, it is one of three standards (alongside the National Fire Protection Association's NFPA 1600 and the ASIS International's ASIS SPC-1) that the U.S. Department of Homeland Security (DHS) officially adopted for its Voluntary Private Sector Preparedness Accreditation and Certification Program (PS-PREP). From December 2010, the American National Standards Institute (ANSI) has approved the ASIS/BSI BCM.01 2010 standard for business continuity management that shares much of the core of BS 25999, while reflecting the differences in the U.S. infrastructure, systems, and terminology.

Other equivalent internationally recognized standards are the ISO/PAS 22399: Guideline for Incident Preparedness and Operational Continuity Management published in 2007 by the International Organization for Standardization (ISO) and the AS/NZS 5050: Business Continuity Managing Disruption-Related Risk published in 2010 by Standards Australia.

BS 25999-1

The first part of the standard, BS 25999-1:2006 Business Continuity Management: Code of Practice, was published by the BSI in December 2006 and provides an overview of the principles, processes, and terminology of business continuity planning and protecting critical functions during times of crisis. It sets out the various stages in developing, implementing, and maintaining a business continuity management system (BCMS) and outlines the requirements for achieving the BSI's business continuity certification.

BS 25999-1 starts by defining the scope of the standard and clarifies that it describes generic best practice that should be customized to the needs and wants of the organization implementing it. It then provides a short overview of a BCMS, describing its various processes, relationship with risk management, and the reasons and benefits for an organization to implement it. Central to this implementation is having a clear, unambiguous, and appropriately resourced BCM Policy and a Programme Management for which the standard defines an approach. This approach, which is perhaps the most comprehensive of all standards, describes the BCM Programme Management as a four-stage life cycle that aims to embed BCM into an organization.

The first stage is labeled "understanding the organization." The organization and its critical activities, resources, duties, obligations, threats, risks, and overall risk appetite need first to be understood before moving to the second stage of designing appropriate business continuity strategies and tactics. The third stage involves the development and implementation of the tactical means (incident management structures, incident management and business continuity plans) by which business continuity is delivered within an organization. The fourth stage is concerned with the exercise, maintenance, and review processes that will enable the business continuity capability to continue to meet the organization's goals. All these efforts should aim not at a BCMS that exists in a vacuum but to become part of the organization's culture and the way that it is managed.

BS 25999-2

The second part, BS 25999-2:2007 Specification for Business Continuity Management, was published by the BSI in November 2007 and features largely the same content as the first part but with greater detail with regard to the specific activities by which a BCMS can be developed, implemented, and maintained. It is organized, similarly to the first part, in four main phases: Planning the BCMS, Implementing and Operating the BCMS, Monitoring and Reviewing the BCMS, and Maintaining and Improving the BCMS.

In the planning phase, the program requirements are determined and the scope and objectives of the BCMS are identified by taking into account the organization's strategic objectives, key offering (products/services), risk appetite, and all possible regulatory or other restrictions. These requirements and objectives form the basis of the BCM policy, which documents the management commitment to the BCMS and should be communicated to all organization members. This phase also involves the allocation of the resources necessary to oversee, implement, and maintain the BCMS; the training and development required; and the processes to manage the documentation and records created as a part of this implementation.

The implementing and operating phase begins with the business impact analysis (BIA), which, according to Section 4, enables an organization to "determine the impact of any disruption of the activities that support the organization's key products and services." The BIA helps the planner to understand the organization's "key" and "critical" business processes (not the same when it comes to prioritizing recovery) and their interdependencies as well as to quantify the potential consequences of an operational disruption in monetary terms. Next, the organization identifies ways to mitigate potential business disruptions by reducing their likelihood, limiting their time frame, or reducing their impact and defines strategies by which it will respond to and recover from them, including relationships with key internal and external stakeholders. These strategies will form the basis for the design of the organization's incident response structure, that is, the identification of people, the development of BCM plans, and the allocation of resources to respond to incidents, trigger an appropriate business continuity response, communicate with stakeholders, and manage the resumption and recovery of business processes.

The monitoring and reviewing phase ensures that the organization undertakes regular independent reviews of the BCMS to determine whether it conforms to planned requirements, has been properly implemented and maintained, and continues to meet the organization's BCM policy and objectives.

The maintaining and improving phase involves the continual improvement of the BCMS's effectiveness through the review of policy and objectives, audit results, analysis of monitored events, and the application of preventive and corrective actions.

Budget Crisis

There are several different types of budget crises that a government may experience; all have as their defining characteristic the fact that a government does not have sufficient funds to continue to operate and meet its obligations. One type of crisis has its roots in politics, as competing political parties become unwilling or unable to work together to pass a budget that provides sufficient funds for the government to continue to function; the U.S. government has experienced this type of crisis several times in the past few decades. A second type of crisis is when a government's revenues are not sufficient to fund its operations and it is not allowed to carry a deficit; some U.S. states and cities were facing this type of crisis as of 2012. A third type of crisis, a currency crisis, is related to foreign exchange rates; this type of crisis is most common in countries with emerging economies, such as Mexico and Chile. Yet another type of crisis is exemplified by the eurozone crisis that began in 2009, in which a government's debt becomes so large in relation to its gross domestic product (GDP) that lenders believe it will not be able to meet its obligations, but the country's choices to resolve the situation are limited because it is part of a currency union including other countries.

Political Budget Crises

In the U.S. political system, the president presents a proposed budget to Congress each year. The budget is modified in the House of Representatives and the Senate, and when a budget is passed by both houses of Congress, it must be signed by the president before it becomes law. Appropriations for discretionary spending (including the military and some social programs) must be specified each year, and most debates about the federal budget involve discretionary spending, although the greater part of the U.S. budget is concerned with mandatory spending for programs such as Social Security and Medicare, also known as entitlement programs.

The power to pass the budget is deliberately shared between two branches of government as part of the balance of powers, but it can raise practical difficulties because budget negotiations sometimes turn into showdowns between the two parties, particularly if one party controls the House and the other controls the Senate, or if the president is from one party and the Congress is controlled by the other party; some less generous observers have likened these negotiations to a game of chicken, in which each party is trying to force the other to blink first.

Between 1980 and 1995, the United States experienced nine gaps during which the previous year's budget had expired and a new budget had not been passed; these gaps ranged from a few hours to several days. For instance, in November 1981, about 240,000 nonessential government employees were ordered to go on furlough (it lasted only one day); in October 1984 and October 1986, about half a million government workers were sent home in the middle of the day but were back at work the next, resulting in a half-day furlough; and in October 1990, national parks and museums were shut down over the Columbus Day weekend because a budget had not been passed to pay the workers. Government shutdowns draw attention to budget issues but are costly, due to lost revenues and the fact that historically federal workers have received payment for furloughed days retroactively; for instance, the General Accounting Office estimates that the October 1990 shutdown cost the government about $1.7 million.

However, the longest federal budget crisis in the United States took place in fiscal year 1995–96, when nonessential services were suspended for a total of 28 days: November 14–19, 1995, and December 16, 1995–January 6, 1996. A report prepared by the Congressional Research Service cited many effects of these shutdowns, including the following: the Centers for Disease Control and Prevention ceased disease surveillance; cleanup of toxic wastes was suspended at 609 sites; hiring of 400 Border Patrol agents was delayed; 368 National Park Service sites were closed, as were numerous national monuments and museums, affecting an estimated 9 million visitors; some 20,000–30,000 requests for visas (from foreigners) and 200,000 requests for passports (from U.S. citizens) went unprocessed; services for veterans were curtailed; and employees of some federal contractors were furloughed without pay.

Budget Shortfall Crises

U.S. states are generally required to balance their budget each year, so they cannot run a deficit as can the federal government. This poses a particular difficulty when the economy is in recession, because tax revenues decline just as demand for government services increases, and political realities make it difficult for legislators to pass, and governors to sign, legislation approving new taxes or tax increases. California is an example of a state that has had to deal with a series of budget crises each year since 2008 and has dealt with them primarily through budget cuts. In May 2012, Governor Jerry Brown announced that the state was facing a shortfall of over $15.7 billion and proposed $8.3 billion in spending cuts, with more cuts to be necessary if voters did not approve proposed temporary tax increases. The effects of the proposed spending cuts include cancellation of most summer school programs for public school students; staff cuts and increased student-teacher ratios in public schools; increased tuition and fees and larger class sizes in the state colleges, universities, and community colleges; involuntary, unpaid furloughs for some state workers; reduced coverage under the state's Medicaid program; reductions in the state's welfare program; and increased deportations of noncitizens held in state prisons.

A demonstration against the Euro Pact in Cadiz, Spain, June 19, 2011, attracts protesters from various cities. The Indignant Movement organized a rally in Madrid against the 2011 Euro Plus Pact, in which some European Union member states would be required to commit to certain political and fiscal reforms such as debt brakes and uniform budget guidelines. The Euro debt, sparked by causes such as unsustainable levels of social benefits and high-risk borrowing and lending, has created an economic crisis in several countries.

Case Study: The Eurozone Crisis

A goal of the European Union (EU) is for all EU countries to use a common currency; the euro was introduced in 1999 (for electronic funds transfers) and 2002 (in physical form) for this purpose. Theoretically, all countries in the EU are required to adopt the euro after meeting certain requirements, but as of May 2012 only 17 countries in the EU have done so. These countries (Austria, Belgium, Cyprus, Estonia, Finland, France, Germany, Greece, Ireland, Italy, Luxembourg, Malta, the Netherlands, Portugal, Slovakia, Slovenia, and Spain) form the Eurozone. There are several competing narratives of the Eurozone Crisis, also known as the European Sovereign Debt Crisis, as well as competing theories as to the best way to resolve the problem. Contributing factors may include real estate bubbles in many countries, trade imbalances, high-risk borrowing and lending, the choice of government to take on private debt burdens, low interest rates on U.S. bonds and Treasury bills that caused investors to seek other investment opportunities, and unsustainable levels of social benefits promised by governments. The phenomenon of contagion appears to be relevant, as a crisis in one country (Greece) spread fairly quickly to several others (Ireland and Portugal) without any changes in the fundamentals of the other countries, and it threatens the ability of other countries, including Italy and Spain, to borrow money at reasonable rates.

The 1992 Maastricht Treaty requires members of the EU to limit their levels of debt and deficit spending to specified levels; however, some countries were able to mask their debt and deficit levels. This problem came to light in December 2009, when Greece announced that its debt amounted to 300 billion euros ($442 billion), constituting 113 percent of Greece's GDP; by contrast, the maximum debt limit allowed in the Eurozone is 60 percent. In January 2000, the EU reported serious irregularities in Greek accounting practices, and the country's 2009 budget deficit was determined to be 12.7 percent rather than the previously reported 3.7 percent; in April 2011 it was revised upward again, to 13.6 percent of GDP.

Although Georgios Papandreou, prime minister of Greece, insisted his country would make good on all its debts, the spectacle of a possible Greek default caused investors to look more closely at the balance sheets of other Eurozone countries with high levels of debt—most immediately, Ireland and Portugal. In May 2010, the EU and the International Monetary Fund (IMF) provided a bailout package of 110 billion euros to Greece; in November they provided a bailout package of 85 billion euros to Ireland, and in May 2011, a 78 billion euro bailout package to Portugal. In July 2011, a second bailout package was provided to Greece, worth 109 billion euros ($155 billion). Although Greece, Ireland, and Portugal have relatively small economies, one fear was that the crisis would spread to the larger economies of Spain and Italy, both of which were being charged high interest rates due to the fear that they would be unable to repay the loans on time; in August 2011 the European Central Bank began buying Italian and Spanish government bonds in an attempt to keep this from becoming a self-fulfilling prophecy.

Delivery of the bailout package was contingent on Greece's adopting austerity measures cutting government services, which were highly unpopular; some economists also argue that the austerity measures are making the crisis worse, because if no one has money to spend, businesses can't make money and thus they will not pay taxes, reducing GDP and making it that much more difficult to pay off the loans. The seriousness of Greece's budget problems is demonstrated by the fact that Greek debt was also restructured in March 2012, with private-sector creditors agreeing to accept only 46.5 percent of the face value of the Greek bonds they held. In national elections held in May 2012, the two political parties supporting the austerity measures, New Democracy and PASOK, received relatively small proportions of the vote while antiausterity and extremist parties did unexpectedly well, increasing speculation that Greece might drop out of the Eurozone and go back to using its own currency, the drachma. Some economists believe this might be a good thing, although it would cause hardship in the short term, because Greece could devalue its currency to make its goods and services more attractive on the international market.

Currency Crises

The world saw several currency crises in the 1990s, including the "tequila crisis" in Mexico in 1994, which affected other countries in Latin America, and the Asian currency crisis of 1997–98. Bates points out that financial crises in emerging market countries (such as Chile in 1982 and Mexico in 1994) differ from crises in mature economies and highlights two major differences: in emerging market countries, private debt contracts tend to have short durations (e.g., one month versus the multiple years common in a country such as the United States), and debt is often denominated in a foreign currency such as the U.S. dollar. Both factors are influenced by the fact that inflation risk is generally much higher in emerging economies than in industrialized countries, and the use of short-term contracts and foreign currencies perceived to be more stable offers the lender some protection from this risk.

A foreign exchange crisis often precedes a financial crisis in an emerging market country: if the exchange rate of the country's currency drops while the debt is denominated in a stable foreign currency, that has the effect of rapidly increasing the amount owed. A currency crisis also affects the ability of individual businesses within a country to obtain foreign financing because it increases their debts and lowers the values of their assets; if businesses do not make money, they do not pay taxes, and this means the government has less money to operate with just when it may need it most. A foreign exchange crisis can also trigger a banking crisis because loans to domestic firms may be denominated in a foreign currency, while the firm does business in the local currency; if the value of the local currency drops sharply relative to the foreign currency, many firms may be unable to pay back their loans. The banks may be forced to cut back on lending, slowing economic activity in the country, and in the worst case a foreign exchange crisis may lead to bank runs and bank failures. The fact that debt contracts are generally of short duration in emerging economies can also magnify the effect of a foreign exchange crisis. While firms in industrialized countries can expect to borrow money for long periods at fairly stable rates, those in emerging countries may need to reprice their debt each month, and interest rates can increase rapidly in response to perceived increases in inflation risk.

Currency crises can spread rapidly from one country to another in a region, a phenomenon sometimes referred to as "contagion"; one example of this type of spread was observed in the 1997–98 Asian financial crisis. The crisis began in July 1997 with the devaluation of the Thai baht and was followed within a few months by currency crises in Malaysia, Indonesia, and South Korea. Although trade linkages are sometimes a factor in the spread of currency crises, Paolo Pesenti and Cedric Tille note that they are not necessary and that a currency crisis may spread even if the countries affected do little or no trade with each other, making the label of contagion questionable, but the term is in common use and its meaning is clear. Several factors may precipitate or facilitate the spread of a currency crisis from one country to another: devaluation of one currency makes that country's exports more attractive on the international market, potentially harming export sales from other countries; creditors may recall loans to country B out of reaction to a crisis in country A, and thus precipitate a crisis in country B, where none previously existed; and because creditors often rely on general information about a region rather than specific and detailed information about each of the countries involved, they may become less confident about lending money to all the countries in a region even if only one is undergoing a crisis.

Foreign exchange crises are often driven by beliefs as well as by market fundamentals, and may become self-fulfilling processes driven by what investors call strategic complementarity: the urge to mimic what one believes others will do. For instance, if one believes that a country's finances are not sound and that other investors will withdraw their funds, one has an incentive to withdraw his or her own as well; if enough people act in this manner, it can create a currency crisis even if there is not a fundamental economic basis for one to occur.

Buildings

As concerns about crisis management increase, owners and operators of buildings have increasingly begun to prepare thorough and systematic ways to respond to crises. Building owners and occupants have long been concerned with crisis management, creating the policies, procedures, and mechanisms to allow them to respond quickly and efficiently to disasters. While historically crisis management has focused primarily upon response to individual situations, recently emphasis has shifted to include mitigation, preparedness, and recovery as well. Although certain natural disasters affect only certain regions of the United States, these are coordinated through central federal agencies that also cooperate with state and local authorities. As a result of these efforts, buildings are better able to respond to a variety of disasters, both natural and human-made.

Background

Buildings can be any human-made structures that are used for occupancy, shelter, or other uses. For over 500,000 years, buildings have been created to provide shelter and other space for indoor work and play. In addition to shelter, buildings provide general living space, privacy, and storage and generally add to the level of comfort of those dwelling within them. Throughout the globe, buildings vary greatly based upon a wide variety of factors, including the availability of building materials, weather conditions, landforms, prices, specific uses, and aesthetic considerations. Historically, most threats were dealt with as they arose, causing a sometimes chaotic and inconsistent response that endangered the safety of both humans and property.

Crisis Management Plans

Builders, owners, and occupants of buildings work to develop plans to assist them in responding to emergencies and disasters. When a crisis strikes, the immediate safety of occupants of a building and a timely recovery often depend upon the existing level of preparedness among all involved. Crisis management plans involve three considerations:

- Protecting the safety of occupants of and visitors to the building
- Safeguarding the contents of the building, including capital equipment, records, and other physical resources stored in the building
- Coordinating with security and other personnel to ensure that an organization's emergency response and recovery procedures are followed

Well-written crisis management plans include procedures that are comprehensive, simple, and flexible and that can be applied to a variety of emergency incidents. These emergency incidents include both local difficulties and national disasters, both natural and human-created. Local emergencies might include such problems as anthrax scares, bodily injury, bomb threats, civil disorder, chemical spills, fires, odors, radiological accidents, snow and other storms, and utility outages. Major disasters covered by a crisis management plan might include earthquakes, floods, terrorist attacks, hurricanes, and tornadoes. At their essence, crisis management plans must focus on three areas: preparedness, responding, and recovering.

For a crisis management plan to be effective, it must be distributed to every building occupant. Before an emergency occurs, it is vital that the plan be known and understood by these individuals. Disseminating the crisis management plan must thus address all building occupants. The plan should be reviewed with all on an annual basis, and new personnel or occupants should be briefed upon hire or upon moving into the building. Multiple copies of the crisis management plan should be accessible in locations throughout the building and organization. Finally, members of the building Emergency Response Team should keep a copy of the crisis management plan at home, in the event an incident occurs when they are not in the building. These copies are best formatted

Case Studies: Two Notable Building Crises and Response

In 1871, the blaze that became known as the Great Chicago Fire destroyed over 3.3 square miles of buildings and killed hundreds of people. Although the origins of the fire are uncertain, it is known that it started in a small barn located on DeKoven Street. A drought prior to the fire, Chicago's reliance upon structures primarily made of wood, and strong winds from the southwest combined to create a situation that caused the fire to spread rapidly. City firefighters reacted slowly to the blaze, in part because of exhaustion from fighting another fire the day before. The inferno burned uncontrolled for two days before rain extinguished it, leaving over 100,000 people homeless. Conditions were exacerbated by the many wooden sidewalks present and by the destruction of the Chicago waterworks, which left the fire department helpless. The mayor declared a state of martial law, and Civil War general Philip Sheridan was placed in charge of relief efforts.

A little more than 35 years later, the 1906 San Francisco earthquake again demonstrated the catastrophic damage that could occur to buildings as a result of a natural disaster. Estimated to have had a magnitude of 7.9 on the Richter scale, the 1906 San Francisco earthquake left nearly three-quarters of San Francisco's 400,000-person population homeless. Although the earthquake itself was highly destructive, many of the buildings were destroyed by fires that started after the initial quake. Over 25,000 buildings on nearly 500 city blocks were destroyed, and the fire department was unable to fight these because the city's water mains had been destroyed. Riots and looting broke out in the aftermath of the disaster, and the U.S. Army was called in to restore order and to assist with the recovery process.

The response to disasters such as the Great Chicago Fire and the 1906 San Francisco earthquake was a revision of building codes to reduce the chances of a recurrence of these disasters. Delays in the reconstruction of San Francisco, however, caused the revised building codes to be made less stringent little more than a year after they were put into place. Plans were also made in Chicago to broaden streets in an attempt to make it easier to combat future fires. Secondary sources of water were secured in the event that water mains were destroyed by natural or human-made disasters. More importantly, builders began to consider how to make buildings that were more resistant to disasters, and city planners and others began to consider how best to respond to and manage crises that occurred.

in loose-leaf binders, prominently labeled on the binding, and stored where easily accessible in an emergency.

Certain emergency response guidelines are relatively simple. All occupants of a building must be prepared to take deliberate and appropriate action in the event of an emergency. For example, many crisis management plans suggest that all occupants know the location of at least two emergency exits in their area and that management keep flashlights accessible in those areas without natural lighting. In the event of an emergency, it is crucial that, before taking any action, occupants ensure they are not endangering themselves. Chemical spills, fires, electrical wires, radiation hazards, toxic fumes, unstable structures, and other hazards must be avoided. A call should be placed immediately to the appropriate fire, medical, or police agency, with the caller prepared to provide his or her name, location, and the nature of the emergency. Occupants must be prepared to remain calm, use common sense, and render assistance as necessary, including being willing and able to evacuate the building immediately at the request of the proper authorities or upon hearing an appropriate alarm.

Developers or owners of buildings can also take steps to reduce risk to occupants and to the building itself. Fire sprinkler systems, for example, can protect occupants and buildings from the risk of fire. Although created in 1812, historically fire sprinkler systems were only installed in buildings that were at high risk of catching fire, such as textile mills and large commercial buildings. In recent years, however, fire sprinkler systems have become much more cost effective and are now found in a variety of smaller commercial and residential buildings. In 1990, the U.S. Congress passed what is commonly known as the Hotel and Motel Fire and Safety Act of 1990, which mandated use of fire sprinkler systems in hotels, motels, meeting halls, or other buildings that are used by government visitors. Although many local building codes do not mandate the installation of fire sprinkler systems, developers who choose to install them often benefit from an array of advantages, including larger floor area limitations, longer egress pathways, and fewer requirements for the use of fire-rated materials. Developers and owners of buildings that include fire sprinkler systems often benefit from lower insurance rates as well. Active fire protection also mandates the availability of fire extinguishers, fire detection systems (such as smoke alarms), and other warning systems. Warning systems can automate the process by which fire, medical, and police services are contacted, thereby safeguarding building occupants as well as the building itself.

Bureau for Crisis Prevention and Recovery, UN (UNDP–BCPR)

The Bureau for Crisis Prevention and Recovery (BCPR) is a division of the United Nations' global development network under the United Nations Development Programme (UNDP). It was created in 2002 as a result of a UNDP Executive Board decision that recognized that "crisis prevention and disaster mitigation should be integral parts of sustainable human development strategies." Earlier, in 1998, the UN General Assembly had decided to "transfer to UNDP the responsibilities of the Emergency Relief Coordinator for operational activities for natural disaster mitigation, prevention and preparedness."

Mandate

The BCPR mandate is to enhance the UNDP's efforts for sustainable development and poverty reduction by working with partner governmental and nongovernmental organizations in order to enhance disaster risk management capabilities, reduce the incidence and impact of disasters and violent conflicts, and strengthen post-disaster governance to establish the solid foundations for peace and recovery from crisis. In a nutshell, the BCPR's goal is to transform the UNDP into a global leader on crisis prevention and recovery.

Specifically, the BCPR's role is to act primarily as a repository for crisis prevention, response and recovery knowledge, tools, methods, and experience that can be accessed and used by UNDP Country Offices, Regional Bureaus, and UN Headquarters whenever and wherever needed. The BCPR is not responsible for designing and implementing crisis programs on its own but provides technical knowledge and financial resources (through the Crisis Prevention and Recovery Thematic Trust Fund or from UNDP TRAC 1.1.3 core funds) to actors and agencies that are present on the ground in support of their crisis prevention, response, and recovery activities. It also has a key role in defining policy for interagency coordination in post-crisis transitions by functioning as a conduit between the humanitarian phase of a post-crisis response (led by UN agencies such as the Office for the Coordination of Humanitarian Affairs, UNICEF, and World Food Programme) and the long-term development phase following recovery (which is the UNDP's responsibility). The BCPR's disaster risk reduction work contributes to the International Strategy for Disaster Reduction (ISDR) and the implementation of the Hyogo Framework of Action (HFA), the international framework for disaster risk reduction. Finally, it advocates crisis sensitivity by working to ensure that the UNDP's long-term development policies and programs incorporate opportunities for disaster reduction and conflict prevention and that the UNDP's commitment to gender equality is reflected throughout these policies and programs.

New Strategy (2007–11, Extended to 2013)

At its conception, the BCPR's substantive activities were organized through seven technical service lines: conflict prevention and peace building; recovery; security sector reform and transitional justice; small arms reduction, disarmament, and demobilization; mine action; natural disaster reduction; and special initiatives for countries in transition. In the first five years of its operation, the bureau has tried to respond to all requests for assistance from UNDP country offices, only to find its human and financial capital stretched thin across a wide range of crisis issues in a variety of countries.

The resulting structure of strategic initiatives was found not to be well integrated, and in 2007 a new strategy was developed for the BCPR's work to focus mainly on (1) select countries based on the nature of the crisis they face and the BCPR's capacity and ability to make a difference through its intervention, and (2) specific prevention and recovery results articulated as "development outcomes" (actual changes in development conditions that UNDP interventions seek to achieve) supported by actions that draw on the bureau's expertise.

As a consequence of this strategy, in terms of prevention, the BCPR prioritizes countries of high vulnerability to natural hazards as evidenced by the UNDP's Disaster Risk Index and in situations facing conflict risk as identified by UN forums. Similarly, when it comes to recovery, the BCPR gives priority to situations where critical national or local capacities have been severely disrupted due to the scale of a natural disaster and situations of priority to the UN Security Council or the Peacebuilding Commission, or where UN engagement has been proposed by the secretary-general. Special attention is also given to those post-crisis countries that receive limited development assistance.

Under the two overarching outcome areas of prevention and recovery, the BCPR has identified nine specific development outcomes to which the UNDP contributes:

1. Prevention (crisis risk reduction):
    - » Development of a common awareness and understanding of crises among key stakeholders
    - » Management of crisis through inclusive dialogue, including traditionally marginalized stakeholders and actors such as women
    - » Strengthening national capacities, networks, and institutions to manage crisis risks

   - Preparation and implementation of crisis-sensitive development and recovery programs
2. Recovery (restoration of a foundation for development):
   - Stabilization of community and personal security situation
   - Inclusion of gender equality and women's empowerment provisions in peace agreements
   - Reestablishment of basic governance functions
   - Revival of sustainable economic activity through the restoration of basic capacities for support for livelihood creation at the community level and assistance in the protection and rehabilitation of productive assets and infrastructures
   - Nurturing of a cohesive social system through the establishment of effective transitional justice mechanisms and the adoption of conflict resolution approaches in the communities

This New Strategy reemphasizes the role of the BCPR as a "knowledge repository" in the field of crisis prevention, response, and recovery that will draw not only from its own work but also from the experiences of all actors throughout the UNDP and the UN system. In this context, the BCPR is developing a Learning Platform on Gender and Crisis Prevention and Recovery in coordination with leading international institutions, such as the London School of Economics and the New York Social Science Research Council. This facility will provide tools and resources to assess on a comparative basis gender and CPR issues at country, regional, and global levels and will facilitate collaboration on gender and CPR issues across the United Nations and with civil society, nongovernmental organizations (NGOs), universities, research institutions, and regional organizations. This platform will also provide training for UNDP staff and will offer space and support for staff think tanks, retreats, reflection, and writing.

Bureaucracy

In strict technical usage, *bureaucracy* is a neutral term referring to the manner in which a complex governmental operation organizes itself, permitting nonelected officials to implement the will of a legislative or executive entity in an effective and efficient manner. In common usage, the term *bureaucracy* refers to an organizational scheme characterized by cumbersome processes and the ineffective and inefficient use of resources. There is a popular perception that excessive bureaucracy has contributed greatly to problems in crisis management, which are partly true and partly perceptual.

Model Bureaucracy

There have been complex government operations throughout history, including the administrative structures of the Roman, Egyptian, and Chinese empires of antiquity. Each of these empires required a means of organizing work over a wide geographic area where workers were separated from the central government, which limited or eliminated the potential for direct oversight. This created concerns that government operations throughout the empire would be handled in an inconsistent manner, creating potential service gaps or the overlap of functions and authorities. To address these concerns, these empires created some form of administrative structure to oversee operations throughout their areas of hegemony. The same has been true of other governments over the years, but the manner of that organization was not studied in an empirical manner until the early 20th century.

German sociologist Max Weber became interested in how complex organizations structured themselves to conduct work. Studying large-scale organizations, he identified a model form of bureaucracy that was both effective and efficient. The model was founded upon a politically neutral leadership possessed of technical proficiency, clearly defined lines of authority that minimized external influence on operations, a scheme for documenting and archiving records of operations, detailed rules that provided for internal consistency by organizational members, and a readily identifiable organizational hierarchy that eliminated overlapping or concurrent authorities and responsibilities.

Weber believed that bureaucratic organizations could be both effective and efficient, but were prey to shortcomings if the principal elements were not adhered to closely. Additionally, he suggested that while the system would be ideal in a stable environment, it was not designed to function well in an unstable environment. Based on Weber's work, this was not a shortcoming, given that bureaucracies were created to achieve the goals set for them by a legislative or executive entity, not to be entrepreneurial in seeking new roles, responsibilities, or authorities.

Modern academic works on bureaucracy suggest that, despite negative perceptions, bureaucracies are more effective and efficient than might be considered to be true by the masses. Such works note that modern bureaucracies often work within narrow legislative mandates that, in some instances, place oversight in the hands of managers selected for political reasons, as opposed to technical proficiencies, thereby violating a basic tenet of Weber's works. These works also suggest that, in some instances, the enabling legislation is so specific that the agency leadership and employees have few opportunities to deviate, regardless of circumstances. Despite this, many modern bureaucracies are as effective and efficient as they can be, within the operational and administrative parameters provided them by the legislative or executive entity that created them. These operational parameters often take the form of detailed rules for internal work processes, which provide for little deviation and limited discretion. As Weber noted, such internal rules may become so extensive that the organization becomes more concerned with following those rules than with achieving their stated goals.

Public Perception of Bureaucracy

In popular culture, the term *bureaucracy* is a pejorative. In common usage, it refers to large, unresponsive organizations, public or private, that are ineffective and inefficient. Bureaucracies are perceived to be entirely focused on internal operations instead of the needs of the public they serve, often treating the public in an impersonal manner. Their operations are viewed as ineffective or inefficient, often bound up in a highly arcane set of internal rules and forms known collectively as "red tape." In many ways, the public perceptions of bureaucracy are reflective of an organization that fell prey to the pitfalls of the bureaucratic structure identified by Weber in his works.

During a crisis, there is a commonly shared vision among the public, the media, and elected officials that public bureaucracies will respond in a wholly unified effort, focusing on the immediate needs of the disaster. Based on a number of factors, including how emergency management is depicted in popular films and books, there is an expectation that emergency management has full authority to acquire resources, make decisions, and work without legal constraint, if only they would demonstrate initiative. There is also a strong belief that the federal government has full authority over all incidents, which is not accurate based upon disaster policies in the United States. If problems do arise, they are often viewed as a lack of leadership, as opposed to being influenced by the legal parameters imposed upon public bureaucracies by the legislatures or executives that created them. These perceptions may contribute to the development of self-fulfilling prophecies that are inaccurate, though, in fact, there have been, and will continue to be, challenges to providing an effective crisis response based on the bureaucratic structures of the local, state, and federal governments.

Case Study: Bureaucracy Problems During Hurricane Katrina

During Hurricane Katrina, a number of problems ascribed to bureaucracies were noted. Illustrative of this, Louisiana's Governor Kathleen Blanco was accused of being nonresponsive for delaying requests for assistance to the Federal Emergency Management Agency (FEMA). In reality, she had requested assistance far earlier than reported, but she had asked for recovery aid, not response aid, and had not followed appropriate procedures for requesting assistance. Because she had not complied with FEMA's administrative requirements, assistance was delayed until the requests were submitted properly, though the need was clear and immediate. Similarly, FEMA had personnel standing by for response who were not permitted to respond without formal orders for deployment, which were not forthcoming, reportedly because President George W. Bush and Secretary Michael Chertoff of the Department of Homeland Security were unfamiliar with specific details of the National Response Plan. Based on internal rules, FEMA personnel who had been pre-deployed to areas near the crisis area were not permitted to proceed into the crisis area without specific orders, which slowed their response. FEMA was also criticized for requiring temporary workers and volunteers to undergo a multiday orientation that included materials on the Equal Employment Opportunity Act and the Occupational Safety and Health Administration, though the workers were needed immediately and most were working professionals with previous training in these areas. However, federal employment laws required federal employees, even temporary ones, to undergo such training, with no waivers for any unusual circumstances, including natural disasters, limiting FEMA's options to do otherwise.

These types of issues have been remedied in some degree by the development of the National Response Framework, which was tied to the Post-Katrina Emergency Management Reform Act, providing for greater flexibility on the part of the FEMA administrator, as well as for increased technical proficiency in its leadership. One frequently noted bureaucratic problem has been a lack of leadership. During Hurricane Katrina, Michael Brown, administrator of the Federal Emergency Management Agency, served as the Principal Federal Officer, responsible for coordinating the response of federal agencies in their support of state and local operations. After a number of problems were identified, Brown was replaced by Admiral Thad Allen of the U.S. Coast Guard. There have been mixed reports of Brown's efforts, but most have been negative, with many concerns tied to his reported lack of technical proficiencies in emergency management or coordinating large-scale, multiorganizational activities. Allen's efforts have often been lauded for their professionalism, based upon his efforts to engage all stakeholders through a unity of effort, as opposed to a unity of command. While working within the bureaucratic structure that existed, he was able to demonstrate strong servant leadership as he supported local and state agencies as well as nonprofit organizations through the use of federal resources. This was noted during post-disaster investigations, leading to a requirement that all future FEMA administrators have professional experience in emergency management.

Bureaucracy and Crisis Management

As a government function, emergency management in the United States is a role shared by local, state, tribal, and federal governments. There is no single agency or individual in charge. Based upon the precepts of federalism, each level of government is largely independent in terms of making its communities disaster resistant and disaster resilient, which is somewhat at odds with how emergency management is perceived by the populace, who believe that the federal government has a leading role and substantive authority in the area. This contributes to an environment where no clear hierarchy exists, where roles are ambiguous, and where rules are inconsistent, which are all reflective of types of problems associated with ineffective bureaucracies noted by Weber. The problem is exacerbated by the fact that there are over 80,000 governments in the United States, if one considers all forms of government, making the alignment of all efforts problematic.

In practical terms, this perceptual issue is exacerbated by the legal framework of emergency management. The basic U.S. disaster model, as framed in the Disaster Relief and Emergency Assistance Act (the Stafford Act), the National Response Framework, and the National Incident Management System, holds that disasters are primarily local events, with state and federal agencies coming in to provide assistance only if local resources have been overwhelmed, which must be clearly documented. This last requirement, as framed by the Stafford Act, is designed to ensure that no federal funds or resources are provided to local and state agencies unless absolutely necessary. In effect, the Stafford Act is a financial fraud prevention act, seeking to limit the distribution of federal funds to local and state agencies, as opposed to an emergency management response act, supportive of a flexible and rapid response to a crisis.

At Odds With Crisis Management

To some extent, bureaucracy and crisis management are at irreconcilable odds. Crisis management demands the ability of agencies to work in a flexible manner in a dynamic environment. However, regardless of how effective and efficient bureaucracies have the potential to be in a stable environment, if the idealized model is realized, they are not well suited for an unstable environment where the situation evolves rapidly. Despite this, the bureaucratic structures of local, state, tribal, and federal governments cannot be wholly eliminated during or after a disaster, for a host of reasons. There are potential means for addressing potential shortfalls. For example, the National Incident Management System provides guidelines to assist agencies at all levels of government to work together if a crisis occurs. Additionally, some research suggests that the adoption of contingent coordination, wherein agencies with overlapping or concurrent jurisdiction voluntarily yield operational authority to others for a temporary period, may help ameliorate interorganizational conflict. It might never be possible to create a bureaucratic structure that will be wholly responsive to the needs of a crisis, but it may be possible to develop organizational leaders capable of working within such an environment in an adaptive manner, contributing to more effective and efficient crisis management in future events.

Business Continuity Management

Business continuity management (BCM) is emergency planning for businesses; if implemented properly, it will help a business recover in the event of a disaster or disruption to its normal day-to-day operation, Some things fall outside the area of BCM; for example, if the disaster is so great that central government takes charge of the recovery, it could be some time before workers are allowed back into a business to start the business recovery process. Another example is if internal business functions fail to perform, for instance, if internal audit or risk or corporate governance fail to do their jobs of protecting the business. In such an event there is not a great deal that business continuity can do. There have been companies whose fall seemed to happen overnight, and the blame was put on one person or one event, but in the cold, hard light of day, common sense tells us that other failures must have been happening in the background to allow a small event to become catastrophic to the business. It should be remembered that no business unit stands alone when considering business continuity management planning.

The purpose of business continuity management is to keep key functions of any business operational during a disruption. BCM is made up of six segments, with project management as the center of the wheel; the point of identifying the processes as a wheel is to underscore the continuous nature of business continuity management.

The six areas of business continuity management are discussed below.

BCM Program Management

Like most new business processes, business continuity starts with program management. When implementing business continuity for the first time, as with any new project, normal project management considerations apply, such as identifying which sector of the business is affected, over what time scale, what are the project deliverables, and are there any "quick wins" (i.e., things that can be done quickly to show management a return on their investment and also that the project plan is on track). All projects need to have assigned responsibility; it may be to a steering group to give the project oversight and to decide what is within the scope of the project. Normally, information technology disaster recovery (ITDR) will be out of scope, as this should be a normal function of the IT department. Remember that all companies or business are political and office politics will play a part, so other managers should be involved as equals—a facilities manager didn't get to be the manager by not knowing the job, and business continuity management is all about teamwork, both in the setup stages of program management and in the stress-filled environment of a full invocation of a business continuity plan.

Understanding the Organization

It is necessary to understand the organization, all the processes, and how each department interlinks with each other in order to understand what the mission-critical activities of the business are. This is done by using a business impact analysis. This analysis asks each business unit or department key questions about how the department operates. These answers will be used later to help develop the business continuity strategy. As a business becomes larger and develops more services or products for its customers, its business departments or business units become more interlinked; sometimes these interdependences are unknown, and if there is a disruption to one of these departments, the effects could be catastrophic. The business impact analysis must therefore ask these questions: What does this department do? How does it do it? Where does the information/product go? Where does it come from? Are there any service level agreements (SLAs) or legal requirements? What are the resource requirements to kept this process going? And what are the time frames? These are just a few of the questions that the business impact analysis (BIA) will ask, thereby providing a process map of how the business works. Having this information will not only help with business continuity planning, as it will be known which departments have mission-critical activities and if there are any single points of failure. A single point of failure is a department, process, or even a person that, if unable to do its job, would stop the other normal processes of the business dead in their tracks. So when developing the business impact analysis, it is important to ask the right people. Senior managers are invariably asked what their department does and how it works; the really danger of this is that unless that manager was promoted from within that department, he/she may not know the specific processes that run that department and which ones need to be recovered—in short, ask the people with the knowledge, not just the ones who are in charge.

Determining BCM Strategy

The purpose of a business continuity strategy is to ensure the business can continue to deliver its products and services, providing mission critical activities with alternative resources within the needed time frames as laid out in a business unit's business impact analysis. The business strategy should cover staff, buildings, technology, and supplies and supply chain (if a manufacturing business).

Staff: The health and welfare of the staff should be at the top of the list. Staff are a key resource;, their knowledge of the business and processes and what their business's customers require makes them indispensable. Recovery teams and those staff working at the business continuity recovery sites will, in the first stages of a disruption, be working for goodwill toward the company. They may have to come to work early or leave late, and the recovery site could be miles away from their normal place of business, thereby adding hours to their working day. With this in mind, ensuring that staff payroll is at or near the top of any recovery list will go a long way toward ensuring that the goodwill the staff have at the start of the incident will still be there at the end.

Buildings/technology: Dealing with a denial of access or loss of a site is one of the key strategies that should be at the heart of any business continuity plan—how business function will be maintained if access to the business or its main site is unavailable. The recovery plans must include measures to deal with this event. If there is no access to the building but the building is still there, it will be known at some point, depending on the nature of the event, when access and business function will be able to recommence normal operation. The BCM strategy may be to send staff home for the day, as a full invocation of the business continuity plan may cause more disruption than the event itself.

If, however, there is a total loss of site, the business continuity plan will be invoked and may run for many weeks. There are key industries in which this type of event causes major problems to recovery planning; these are business that need clean rooms, such as food manufacturers, technology companies, and drug companies, all of which use clean rooms in their product manufacturing processing and all of which are very difficult to find in recovery sites that are not built with the company in mind. Technology covers many areas, such as office computers, laptops, or servers, or telecommunications that a business needs to talk to its customers, stakeholders, or even staff at other sites to ensure that the recovery process is not delayed. Specialist technology may be needed for the business processes, and what would happen if this technology were lost and what mitigation could be done to soften the effects of its loss should be considered.

Supplies and supply chains: It is the nature of world trade that there may be components in the manufacturing process that come from all over the world. What would be the effect if this supply chain were to be disrupted by natural disaster? What if materials cannot make it to the factory in time for a "just-in-time" supply chain? Is there a stockpile of core components just in case there is a disruption, or a list of other local suppliers who could step in if needed? It may be necessary in a disruption to acquire components locally at higher cost to ensure that there is as little disruption to the customer base as possible. This cost can be recovered if it is included as part of the disruption insurance.

Developing and Implementing a Response

There needs to be a process in place for the invocation of the company's business continuity plan; this is normally done by the incident management or crisis management team. They are a group of senior managers whose role in a disruption is to manage the incident and the work of the recovery or business continuity teams. There tend to be three levels of incident management, which reflect the same structure as the emergency services. While the emergency services use "gold," "silver," and “bronze” to label their command structures, in business continuity, “strategic,” “tactical,” and “operational” are used. At the strategic level are board members, who have to make strategic decisions on how a disruption is to be handled; at the tactical level are senior managers, whose role is to manage the recovery of the business and report to the board but who also set the goals of the operational teams; and finally are the operational teams, whose job it is to fix or manage the disruption. These are also the business continuity recovery teams who will be at the work area recovery (WAR) sites, running the mission-crucial activities until the disruption has been dealt with or until most if not all the key activities are being run from the recovery site. When a business continuity response has been developed for processes, it should be asked if the cost of the response is more than the cost of running the processes. If the recovery cost is more than would made from the process, it must be asked, “Is the recovery doing more harm financially than if the process weren’t recovered?”

Exercising, Maintaining, and Reviewing

Any business continuity plan that is not tested is an unknown and more than likely will fail, because if it is not tested, any weakness within it will not come to light until it is too late, and staff and key managers will not be certain of its implementation. Because of the ever-changing nature of business, it is important to annually, if not more frequently, review the business continuity plan to ensure that it is up to date and reflects the business or department it is designed to recover.

Embedding in the Organization’s Culture

If an organization has a business continuity plan but none of its staff know what it is or their role within the plan, the chances of its working are low, to say the least. Staff should be told not only what the business continuity plan is but also what their specific role is within the plan. This can be done in many ways, such as an internal company newsletter or magazine, a monthly update on business continuity, or by having a business continuity awareness week. Staff could be e-mailed and informed of any new business continuity roles within the company, or there could be town hall–style meetings with staff to inform them what business continuity is all about. There are many ways to inform staff—companies just need to find what works for them and then do it.

Business Continuity Planning

In today’s world, almost all companies have some level of planning that addresses their awareness of the possibility for events to occur that will cause a disruption in their operations. This has become known as “business continuity planning” and typically focuses on the infrastructure needs of an organization. Companies spend a great deal of time ensuring that all of their equipment will be able to function following a critical event; however, very little time has been focused on planning for the people who would be managing that equipment—that is the human component of business continuity and is the key to any successful plan.

Multiple factors need to be taken into consideration when planning for the human component and whether or not someone will be able to work following a crisis. These factors can be identified either as having a physical impact on individuals’ ability to work or as having a psychological or physiological impact on individuals that interferes with their being able to work to their pre-crisis level. In order to explain how these factors can impact an individual, this article uses a case study of a hospitality organization with properties in the city of New Orleans and the impact that Hurricane Katrina had on its employees. Critical lessons were learned as a result of Hurricane Katrina at all levels, including individual, organizational, and local and federal government.

Although there was capability to provide advance notice that Hurricane Katrina would make landfall on the Gulf of Mexico shoreline, few were prepared for the devastation that occurred as a result of the breaches in the levee system surrounding the city of New Orleans. Businesses in the immediate vicinity were able to survive the initial effects of the storm coming onshore; however, the failure of the levee system with its resulting flooding was insurmountable for most.

Physical Impacts

With Hurricane Katrina threatening to potentially be one of the most destructive hurricanes in the history of the United States, New Orleans mayor Ray Nagin called for a voluntary evacuation of the city at 5:00 P.M. on August 27, 2005, and subsequently ordered a citywide mandatory evacuation at 9:30 A.M. on August 28. The evacuation ordered by the mayor was not mandatory for hotels in the area.

On August 29, the center of Hurricane Katrina passed southeast of the city of New Orleans. Initially, hotels in the area reported flooding on lower levels of their properties due to the storm surge. Reports from the properties indicated that they were able to relocate guests and supporting facilities to higher floors. Employees who were at work when the storm hit were unable to leave when their shift ended. Staff who were scheduled for subsequent shifts reported a lack of transportation and inaccessibility that limited their ability to report to work. Many of the major roads suffered some damage. As a result, the employees at the hotel were enlisted to stay on extended shifts to ensure the safety of the guests and provide amenities as available.

Because hotels were still able to provide shelter to the guests who had remained at the properties, they began reporting the need to address security issues that were developing. Several properties reported people other than guests attempting to enter the premises. Staff were instructed to lock down the properties and to place sheets over the windows to keep them from being visible to people outside on the streets. Staff also reported that local government agencies were exercising their right of eminent domain and inserting their operations into the hotel properties.

Communication is a critical component during an emergency situation. During Hurricane Katrina, the infrastructure supporting telecommunications was compromised. Cell phone towers were inoperable, and land lines were minimally functioning. Lack of means of communication resulted in increased difficulty in accounting for guest and staff status and location. The hotels utilized an emergency call center located outside the affected state as a central communication link for all properties along with their headquarters operations. This link was crucial in identifying those guests and staff who were unaccountable for and was able to place outgoing calls to contact numbers that had been documented prior to the incident. It also provided a connection between the hotel's emergency response team located at their headquarters and all of the properties that were impacted. Updates on the status of the properties and the events unfolding in the city as well as the emergency response were able to be processed via this two-way communication link.

As the flooding from the breached levee system increased, evacuation became imperative for safety. Buses and trucks were brought in to move people quickly out of the affected areas. Because of the critical nature of the situation, people boarding these transports were not always aware of their final destination. Staff from the hotels were widely scattered throughout the United States and, as a result, a number of concerns developed. First priority was assessing the status and location of their staff and connecting them with their family members. The hotels utilized a variety of means to contact their staff and their family members. They sent notices to the various support centers providing the emergency contact numbers for their company. They used radio and newspaper announcements to distribute the emergency call center number. Once the hotels were able to account for all of their staff, coordinating logistical support was next. Because many of the staff were no longer in the state of

Louisiana, identifying who could report for work and whether they could work at other properties, how to pay the staff, and how to access banking accounts and medical benefits quickly became the focus for management.

Psychological Impacts

When explaining the psychological responses of individuals during a crisis situation, most studies utilize Abraham Maslow's hierarchy of needs theory, which was first introduced in a paper by Maslow in 1943. This theory identifies four levels of basic human needs and suggests that the basic levels need to be met prior to an individual being able to focus on attaining the fifth and highest level. Many of these levels can occur at any given time, although there is some requirement to have the base levels fairly well met prior to an individual being able to focus any energy toward attainment of the higher levels.

During a crisis, the very base level—which includes those staples that sustain human life—is the immediate necessity. Food, water, air, sleep, and physiological homeostasis make up this foundation. Initially after Hurricane Katrina making landfall, these items were available at the hotel properties. However, the next level—which focuses on issues connected to safety of the individual, property, and family—was compromised. The staff reported witnessing looting, violence, buildings burning, and the sound of gunshots just outside the hotels. With the majority of the attention of the authorities focused on the rescue efforts, their sense of safety as well as the inability to contact family members and assess their safety became cause for concern.

In this situation, the insertion of police personnel into the properties provided the protection necessary to achieve a sense of personal safety for guests and staff. Staff later reported that the sharing of their resources with the police personnel provided them with a sense of connection. This connection, along with the contact with management at headquarters, was critical in their ability to keep from being overwhelmed by their circumstances. Staff also reported that their initial sense of helplessness with regard to the crisis diminished as they were able to provide basic amenities such as food, shelter, and safety to the guests as well as to the police.

Response

In addition to understanding how Maslow's hierarchy of needs theory is manifested by people in crisis, current disaster response literature also includes the concepts of vulnerability and resilience with regard to the individual's ability to cope with a disaster. There appears to be some relationship between vulnerability and resilience; however, additional research is indicated to further identify the connection. Some of the most vulnerable communities have been able to exhibit significant resiliency following disasters, including the city of New Orleans.

Resiliency is connected to the ability of an individual or a community to recover from a disaster and is a direct reflection of the level of planning and preparedness that happens prior to the occurrence of a disaster. This planning and preparedness needs to be addressed on the personal level as well as the organizational/community level. Developing the emergency response plan is one of the first steps in emergency response preparedness, but it is only the first step. Testing the plan will help identify whether it is operational for the organization and whether it has any shortcomings. It has been evidenced, however, that even with planning and preparation at all levels, another factor, adaptability, plays a significant role in survival following a disaster.

Flexibility is a critical factor during a crisis and results in being able to adapt to situations as they arise. Crises vary from hour to hour as the events develop, and the impact experienced by those affected will also tend to vary. The organization and its staff need to be able to recognize the changes needed in order to support the response. However, due to the physiological and psychological impacts of stress, people may have a difficult time learning new behavior in the middle of a crisis. Requesting someone to complete a task that is outside his or her usual routine will require more information and guidance than usual.

The duration of the crisis and the level of destruction definitely impact the resiliency of an individual or a community. Because of the massive level of destruction of property along with the significant number of deaths that resulted from Hurricane Katrina, the negative impact on the resiliency of the community and of individuals was devastating.

Army National Guard members help New Orleans citizens into evacuation buses after being stranded for three nights at the Hyatt Regency Hotel downtown after Hurricane Katrina, September 3, 2005. Local hotels experienced severe disruption, not only to their infrastructures but also to the human component of their businesses, which is needed to keep a business continuity plan running. Staff were unable to come to work or were evacuated to unknown destinations, communication was compromised, and security issues developed.

Physiological Factors

The effect of stress on the human body is another component for discussion and education when addressing the human component of business continuity. At the time of a crisis, being able to provide people with information about the body's response to stress can normalize their experiences and have a calming effect. Even in major disasters, this information can help people regain some control over their responses in an out-of-control situation. However, very few organizations consider how a crisis may affect the ability of the staff to fulfill critical roles at the time of a disaster. In the case of the hotel management being disconnected from their staff at the properties during Hurricane Katrina, having some information on the impact of stress on their staff helped them to support their staff appropriately so that they could handle the challenges they faced.

When a crisis occurs, a number of natural and normal internal processes are put into motion. Numerous articles and studies have addressed the acute stress response first described by Walter Bradford Cannon in 1932. Otherwise known as the "fight-or-flight response," his theory explains how the physiology of animals, including humans, responds to a perceived threat. The main focus of this theory is on the sympathetic nervous system. This system plays the primary role of regulating the homeostasis of the organism. It accomplishes this by direct connection to almost every organ system in the body. Additional research has identified a "freeze" component to the response that is exhibited just prior to the reaction to the threat. By understanding this and being able to provide information on this natural response, an organization can help reassure staff that their responses are very normal given the very abnormal circumstances. Also, this normalization for the experienced responses can help assuage the guilt, blame, and anger that may result from misperceiving the actions of others.

In addition to the acute stress response, knowing that people can be present but not fully functioning because of fear, concern for family, and exhaustion is especially helpful when communicating information. The ability to concentrate is taxed during a crisis and results in the need to repeat information and to inquire about any questions with regard to the information being communicated. Organizations can plan for this interference by developing documents to be utilized during a crisis that cue the user for specific information and questions. Information sharing is additionally challenged by all of the false information or rumors that may be shared during a crisis. Bringing these rumors to the surface for discussion is an important piece of the communication between staff and management.

Recovery

On September 5, 2005, almost one week after Hurricane Katrina made landfall, all properties reported that all guests and staff had been evacuated. However, efforts continued to be necessary to account for their staff as well as their status and locations. Once the primary needs for survival and safety were met and families were reunited, management was able to shift its focus to logistical concerns regarding identifying locations for staff that were available for work, paychecks, and benefits, along with ongoing communication in general.

Part of the recovery process following Hurricane Katrina included continued monitoring of the health of the staff and management. Initial debriefings provided a means for people to share their experiences and gain some understanding of the overall response, especially at the staff level. Additional meetings that focused on the organization's emergency response teams and management provided support as well as time to discuss areas of concern. These teams often reported a greater sense of responsibility and frustration at the time of the crisis due to the fact that the teams were the liaison between the organization and the events going on at ground level.

Lessons Learned

Following a crisis that has had a significant impact on an organization, an after-action review of the plan and the processes in light of the issues that surfaced during the response is considered to be a best practice in emergency management. Identifying areas where additional definition and focus are needed as well as integrating information from the response increases the value and integrity of the plan. Numerous changes in operational processes resulted following the aftermath of Hurricane Katrina with regard to business continuity that took into account the human component. Changes occurred at all levels within the organization and also on an individual basis.

On the organizational level, evacuation and shelter-in-place protocols were reviewed and internal decision-making processes were updated. One of the most problematic issues that surfaced during Hurricane Katrina was the inability of management to communicate with their staff and assess their status, locations, and any needs that were identified. The ability to connect with staff is the critical piece of the human component of business continuity. Knowing who is available for work and providing details about alternative worksites and accessibility of those properties in the affected area helps restore the operations of the organization. Updating personal and emergency contact information on an annual basis at minimum is crucial for effectively maintaining connection with staff.

Inclusion of other organizational departments, such as human resources, security, risk management, and information technology (IT), in addressing the human component of business continuity ensures that the impact of future crises is mitigated.

One significant obstacle reported during Hurricane Katrina was the difficulty in receiving paychecks and/or accessing banking accounts. Organizations can educate their staff on the benefits of having paychecks directly deposited into their banking accounts and making their funds available from other locations. Another difficulty reported was the inability to access medical treatment within their insurance network. Many of the staff were relocated outside the state of Louisiana, which placed them in an out-of-network situation with regard to their health benefits.

Knowing that this is a possibility during a crisis and having discussions with the health care providers regarding a backup plan for prescriptions and medical treatment is another aspect of preparedness planning.

Part of the organizational planning should include increasing the awareness of staff of the importance of developing personal emergency response plans. After Hurricane Katrina, the government authorities made strong recommendations for all individuals and families to create their own emergency response plans. Recommendations on components for a personal emergency response plan include disaster supplies, an evacuation plan with a predetermined point of assembly, and a communication plan to assess the status of all family members. The inclusion of the human component into the business continuity planning will result in a robust and functional emergency response plan.

Business Continuity Planning Life Cycle

The business continuity planning life cycle (BCPL) is used to implement and maintain processes that ensure the continuity of business functions. The BCPL is a process that consists of phases named analysis, design, implementation, testing, and maintenance. Using this process, the BCPL can provide contingency processes for various parts of the organization to use under crisis conditions such as a power outage or immediately after a fire or flood, anything that would interrupt the normal flow of activities in part or in whole. In short, the crisis management process would use the results of the BCPL to help an organization operate under crisis conditions.

The BCPL Process

The BCPL process is to analyze the flow of activities to determine if there are points in the flow at which something may interrupt or degrade that flow. At times, no analysis is needed because an adverse condition presents itself and the response is used to develop plans to handle the adverse condition in the future. Without an adverse condition, the analysis carefully reviews the flow of activities, looking for people, devices, or other resources that are single points of failure (SPOF) or a point in the flow where an interruption cannot be handled by existing processes. For example, an SPOF is a single fax machine that is required to complete the flow of activities. Should that fax machine break and there be no alternative processes, activities would come to a halt. In addition to the SPOF, there are levels of degradation in activities that present a problem for the organization in that it cannot meet deadlines.

Analysis Phase

Business impact analysis (BIA) is a more formal name for the BCPL analysis phase. The BIA is an interview and survey process that discovers which activities are most important to the organization. The BIA prioritizes the activities and gathers information on how much the organization would suffer if the activities could no longer be performed. The suffering is usually quantified in terms of loss, such as lost revenue and additional cost, but can include other measures of suffering. The final BIA summarizes the prioritized activities and potential losses for decision makers within the organization to review, modify, and approve with a spending threshold–based potential loss. This yields the next phase of the

Case Study: Client Support Planning

A company that hosts computer software for clients with 24/7 operations reduced costs by not having its systems engineering staff of six at the workplace 24/7 to provide support should the software break down and result in client support calls. Because the hosted applications deal with the life safety of patients, on several occasions a client had to initiate its crisis management processes to deal with the outages. Instead, the company placed engineers on call for client support; the engineer would be notified of the call by the 24/7 help desk. The on-call person would have a cell phone and laptop computer to provide support. Other engineers had no company-provided equipment to take home.

Issues arose when the on-call engineer was interrupted in the ability to support client calls by becoming ill or experiencing a family emergency that tended to override the engineer's ability to support the client calls. The on-call engineer would call for backup, but the backup engineer would need to go to the workplace to provide support because the disabled on-call engineer could not pass on the cell phone and laptop. Issues also developed when multiple failures occurred, forcing clients to wait while the single on-call engineer moved from one problem to another. In most cases it was faster to let one client wait rather than call an additional engineer to travel to the workplace to lend additional assistance.

To attract more business, the company instituted service level agreements (SLAs) with new and existing clients. These SLAs had monetary penalties averaging $1,000 for each hour the company failed to meet the SLAs. The penalties could multiply quickly if multiple clients experienced outages at the same time. This change increased the visibility of the engineering support problems and initiated the need for a better support structure.

The BCPL was initiated to analyze and address the addition of SLAs to the support function as well as various other functions related to the prevention of outages, such as software and hardware upgrades. This case study concentrates on the engineering support function.

During the analysis it was discovered that the average monthly on-call support was 24 hours and involved 12 clients and just four systems. There were four cases of multiple problems happening at the same time, so one client had to wait until the on-call engineer finished correcting one problem and could move to another; this delay was 0.5 hours. The average individual client outage was 0.5 hours, with some as long as four hours.

Considering the impact of SLAs, it was determined that an average long outage would cost $4,000, the average outage was $500, and the minimal total monthly cost would be $24,000. The financial department was consulted to determine an acceptable level of cost, since outages can be reduced but are unavoidable, and the acceptable cost was $3,000 per month; a spending threshold of $10,000 was approved, as well as $1,000 in monthly recurring expenses.

The engineering staff thought they could reduce the overall outages from 24 hours to 12 hours using different methods to prevent outages, leaving the 12-hour unavoidable outage at a cost of $12,000. Subtracting the acceptable $3,000 cost left a $9,000 probable monthly cost in SLA penalties.

The engineering team was consulted to understand the current process and to determine how the outages could be further limited and the estimated SLA penalty costs reduced while keeping within the $10,000 spent and the $1,000 recurring cost. The analysis and design and implementation phases of the BCPL happened at the same time in this case because the solutions were relatively simple to identify and implement.

Several requirements were identified, including the need to react more quickly to problem calls and to avoid client wait time for multiple concurrent problems, and the ability to more quickly fix the most common problems. Considered the biggest risk, the team obtained three on-call cell phones and three on-call laptops for $5,500 to be used by the six engineers on a rotating schedule so there would always be at least two engineers a phone call away. In order to respond more quickly to problems, it was determined that a software product could be purchased for $2,000 and $100 per month licensing fees that would test the server for a heartbeat, and if the server did not have a heartbeat, the software would send a text message to all on-call cell phones and an e-mail to the help desk. Heartbeat software investigates a server using several different methods, and if none of the methods works, the server is probably having problems. This heartbeat check is estimated to subtract on average 15 minutes from each call, as it takes between 5 and 15 minutes for the user to realize he/she is having an outage and initiate the call to the help desk. The analysis also identified that 40 percent of the issues reported had to be fixed by rebooting a server that usually hadn't been rebooted in more than a month, so the servers were programmed to automatically reboot themselves on a monthly basis. The clients agreed to this average 15-minute outage and agreed it would not count toward the SLAs because it was a planned outage.

Once all the equipment and software was purchased, the engineers did some testing to ensure each process worked as designed. As client problem calls arrived at the help desk, the on-call engineers were either already working on the problem or ready to work on the problem. The processes worked well for months, reducing the overall averages for outages to four hours affecting five clients and three systems. In some cases the heartbeat software notified engineers in time to have the problem fixed by the time the user called the help desk.

As time went on there were instances of weather so severe that the engineers could not safely travel to work. Adding to the problems, many times the severe weather would affect the servers, requiring quick response from engineers who could not make it to work. While the on-call engineers could handle the problems, the delays due to the reduced staff ran into as much as $35,000 in SLA penalties.

The BCPL was initiated again. The analysis phase was short, as the SLA penalties made it obvious that each engineer must have the capability to work from anywhere there is an Internet connection and that the company needed on-call support from contract systems engineers for larger outages. The decision was made to provide every engineer with a laptop and a cell phone and also to contract with a consulting firm for additional on-call help to be contacted when needed and to be paid by the hour. During large upgrades, an engineer would remain on-site off shift to be ready to handle client calls and call for support if needed.

In addition, some of the minor problems were so simply fixed that some instructions were given to the help desk to fix, allowing engineers to work on more complex problems and providing a career path from help desk to engineering. Last reports showed that the problems were reduced to two hours affecting three clients and three systems. Several severe weather events occurred with no noticeable degradation in service or increase in SLA penalties.

In order to maintain the efficacy of the work-from-home strategy, the engineers on call work from home the entire scheduled on-call duration and find it a job perk.

Case Study Analysis

This case study shows two forms of continuity strategies. The most apparent strategy was the BCPL development of a robust work-from-anywhere process for the systems engineers, the testing of the processes, and the successful maintenance processes enhancing the work-from-anywhere processes for all engineers. The second continuity strategy was instituting SLAs. Without the SLA penalties, the company would have had little impetus to improve its call handling processes and would have continued to have issues handling the outages in a manner acceptable to its clients.

BCPL potential interruptions to design for and a spending threshold that cannot exceed a certain percentage of loss.

Design Phase

The BCPL design phase takes all the analysis information and develops an iterative process of designing solutions to the potential interruptions that fit within the spending threshold. As solutions are determined, the options are validated by the people performing the activities and brought to decision makers for review and approval. After final approval, the designs are taken to the next BCPL phase, implementation.

Implementation, Maintenance, and Testing

The BCPL implementation phase schedules activities that implement the design. In some cases this can be a complex process requiring a project manager, purchase of equipment, moving of departments, and perhaps even some short, approved interruptions to the activities to realize the final implementation. After the BCPL implementation, there is a maintenance phase of acceptance and periodic testing.

The BCPL acceptance should be smooth if the implementation went according to plan, but there can be difficult implementations that require a return to portions of the design phase to modify the final solution. Once the final solution is firmly in place, it is tested and accepted if all goes well. The BCPL solution is maintained through testing. It is always advisable to test things that are infrequently used to ensure they will work as designed when they are actually needed. Testing can happen on strictly a periodic basis such as twice a year, or it can be triggered by changes in the activities the solution was designed for. The best way to test a BCPL solution is to test it after a significant change to the activities the solution was designed for. Testing should exercise all aspects of the BCPL solution and formally document the results. This way the new activities can be worked back into the solution by returning to phase one of the BCPL. Because the BCPL solution is infrequently used, the testing usually uncovers some part of the solution that does not work as well as expected and requires a return to phase one of the BCPL.

The contingency processes resulting from the BCPL can be invoked from the crisis management processes. When a crisis occurs, often there are outages of business processes that would be mitigated by the results of the BCPL.

Conclusion

Contingencies developed using the BCPL can be used by the crisis management process to overcome outages and interruptions for clients who care for patients and for every organization. The case study shows that the crisis management process would invoke the work-from-anywhere processes to help support clients.

Business Impact Analysis

The business impact analysis (BIA) is a core component of any business continuity plan, or business continuity management system. The business impact analysis does exactly what it says: it assesses the impact to a business during a disruption, whether it is a denial of access due to loss of buildings or being unable to enter premises; loss of key systems, due to loss of information technology (IT), telecommunications, or Internet connection; or loss of key personnel, such as board members or key members of staff.

The business impact analysis describes how a business actually works, not how it is assumed to work. It analyzes how processes come into a department from upstream and what happens to those processes in this department to enable them to move downstream. It is effectively a process mapping of a business from a risk and disruption point of view.

Although there are many different types of business impact analyses (some in Word documents, some in Excel spreadsheets, some in specialized business continuity software), they all ask fundamentally the same questions: What is the role of a given department within the business? How does the department operate? Where does the information required to perform these processes come from? Were does that information go? Are there any service level agreements (SLAs) in place within the business, or with suppliers or customers? Are there any financial or legal impacts to the business if these processes are delayed? How much financial loss does that incur on the business?

A BIA is completed at the start of any business continuity management system to ascertain exactly how a business functions, and there is little point in doing business continuity planning without having the fundamental building blocks in place: how a business works, how departments interlink with each other, etc. A business impact analysis accesses this, enabling a business continuity plan to be produced that will work. The BIA also identifies single points of failure; these are processes or a department that on their own do not stand out as key, but if they were to no longer function, the knock-on effect to the business would be disastrous.

Having considered why a business impact analysis should be completed, now consider how the BIA is produced. It should be remembered that this is only a guide, as each industry has unique processes or departments, obvious examples being nuclear power or medical research companies that may have departments with very specific features and therefore require adaptations to the normal BIA template. Because businesses are complex, it is important to get the right information. This can be done by holding a series of interviews; it is, however, key to the success of the business impact analysis to make sure the right people are interviewed. For example, it may be necessary to interview the director of a department to get the strategic overview of the department, then the manager to get the operational point of view, and then the agent or person who is performing the process. They will describe what happens and what is needed to make the processes successful and where it goes when it leaves the department. They will also know any shortcuts to the process and what information is needed from other departments; in each department there is always one person who knows the processes and the department thoroughly, and this is the person ideally to interview.

The completed business impact analysis covers the following areas:

Information: This section of the business impact analysis lists what department it covers, what processes it operates, who was interviewed, and when. The reason for this is both to have an audit point on the BIA against which all others will be checked, and the name of the person interviewed so that if a problem arises, it is possible to go back and reinterview the original source of the information. It is true that most managers will delegate this task to one of their employees. At the end of the interview, a department business impact analysis should be completed and signed off by the manager; again this is part of the audit trail. Be aware that all businesses are political, even if they think they are not, so each manager will emphasize how important his/her department is; it may be necessary to allay any fears they may have in order to get to the right information.

Business activities: This lists the departments, business activities, and processes in the order of priority in which the department places them. It should also list the frequency of each process or activity: Is it a daily weekly or monthly process? What type of process is it—support, operations, legal? What is the recovery time for each process—five minutes to one month? Include any notes about a process, thus giving a snapshot of the department.

Financial: This looks at the direct losses for revenue and operations for the department over a set time period, from one hour to 10 days, and also indirect losses. These could be delayed production or a service level agreement or even cover the cost of dealing with the backlog of work that has developed because of the disruption.

Nonfinancial: This covers the effect of the disruption on company image, human resources, and regulatory or legal issues. Compliance can be added to this list, but the point is to look at the severity of impact over 1–10 days and at the level of impact from none to low, medium, or high. It is important to ask these questions because some disruptions that have had a negative effect on a business had no impact on its financial operations at first but had a very negative effect on the business in the days following the disruption.

Risk: Each department needs to look at risk—not financial risks but threats that may be of concern to the department. These threats can be listed, with likelihood and potential impact and maybe any notes. Threats range from power outage to natural disaster to fraud to terrorism; the severity can be graded from 1 to 5 or 1 to 10 for the impact and also for the likelihood. This is done for each department throughtout the business, and at the end of the process, a threat matrix for all the departments is completed. The threat with the highest number is one that will have the most impact; it, however, is also the one that is least likely. This information will drive the company's risk management strategies, and it is worth noting that any risk assessment would have to look at the environment in which the business was located; for example, petrol stations near the business would present a risk of fire and explosions. This would form part of the executive summary of the BIA report.

People: It is important when talking about how many people are needed to keep a process going during an event to remember that this is not always the same number that are needed during normal business operations. A department may have 25 staff working on a process, but in an event they may be able to get by with two for a limited time. So it should be asked how many perform processes during normal business operations, then how many are needed during an event to kept the most important process going, then how many extra people will be needed over a 10-day period. Each day that goes by that the department is not fully working means a backlog will accrue.

Alternative working/manual working: When asking about alternative working, caution should be taken to consider who is being asked, because as a manager moves around a business or up the management ladder, he/she will remember a time when a given process could be done manually. But as technology evolves in business, processes that were once fully manual may now involve some form of automation. With this in mind, it should be asked: Can this process be performed at another site? If so, is that site able to do this process? And what will be needed, that is, PC/laptops, Internet? Are there any vital records or templates that may be needed? Are procedures for doing this process manually available? Is it documented? And, most important, are the staff trained in these procedures?

Dependencies: Departments within a business do not run in isolation from each other; they all pass information or interact on a process. This process may come from upstream and through a department to be passed downstream. The reason these interdependencies are mapped is to determine the effect that having a department nonoperational will have on the business. Will one department that is not seen to be that important be critical to the key process of the business? Mapping out the interdependencies develops an understanding of the relationships between all departments and also highlights potential points of failure. A single point of failure is a process or department that would bring the business to a standstill if it were unable to operate normally,

Recovery time objectives: Recovery time objectives (RTO) apply to computer applications, telephony systems, or any automated system. It must be ascertained which systems a department uses, whether it is e-mail, Internet, or any other in-house software that is required to run or manage a process and whether, over a time frame of 1–10 days, the loss of this system would be manageable, disruptive, critical, or catastrophic. This information indicates the gap (if any) between what the business needs and what IT can deliver, and over what time periods (remember, IT is there to support the business, not the other way round).

Recovery point objective: Recovery point objective (RPO) is the point from which data need to be recovered following a disruption to the department. The department must determine what level of data loss, if any, it can handle once IT systems are back up and running. Can the department cope with data restored from the start of the working day or when the event happened? How much data can a department afford to lose?

Office: This section of the BIA specifies what the department would need to set up and run from another building or recovery area; for an example, over a time frame of 1–10 days, how many PCs, chairs, desks, and phones would the department need on day one just after the disruption through day 10, when a large number of processes should be recovered. Some departments will only have a fraction of their normal needs because their staff will have other roles during the disruption. Facilities management and the IT department may have most of their staff at the scene of the disruption trying to fix the problems and hence won't need that much office space at the recovery site.

Vital records: These are records that the business or department needs; they could be templates or contracts, so it is vital to know where they are. Are they on a system or server? If so, which one? This information is needed so IT can make it part of their disaster recovery plan and be able to back this information up in order to have copies at a recovery site, and if a department process needs this, it needs to be easily located.

Wrobel, Leo A. *Business Resumption Planning*. 2nd ed. New York: Auerbach, 2008.

Business Resumption Planning

From the inception of the concept of business resumption planning, there has been much confusion over what is meant by the term. Many confuse it with business continuity planning; compounding this problem are business resumption planning templates on the Internet that, apart from the title, are in fact business continuity planning templates. The two are not the same, and confusion is only increased when the term *return to normal service planning* is introduced. It is little wonder that there is so much confusion surrounding the jargon. Business resumption planning is the planning required to return a business or organization from the state of having had an incident—during which a business continuity management was implemented—to a state of normal business.

In the linear process of business continuity, first there is risk management, which is identifying, classifying, and, where possible, mitigating risk to a business. Second, there is incident management, which is dealing with the incident, activating continuity plans, bringing in key personnel, and dealing with the initial effects of the incident. The role of a business continuity plan is to maintain key core processes and services, both internally and externally, to key customers at an agreed service level. This service level will be, by its very nature, lower than normal business levels. Finally, there is business resumption, where business goes from a state of recovery and all that entails, to a state of normal business and operates in a way that is consistent with operations before the incident. Each stage of this process has to be considered as an individual planning scenario that links everything else. The question, "how do I do that?" must always be asked and never assumed. Everything must be verified in order to avoid the pitfalls that may be encountered.

From Continuity to Resumption

Business continuity plans are run from the recovery site; when the incident is over, staff and processes are moved back to the normal place of business or into new premises. During a very short incident—for example, only a few days—this is not difficult, because in effect, the company is running its business continuity plans in reverse. However, if the company has been working at a recovery site for a number of weeks, the process is more complex.

This is because the driving factors that were in place when the business continuity plan was activated are no longer driving factors in the resumption plan, since the incident is no longer imminent and providing the impetus to force staff to make decisions rapidly. If the incident was prolonged, the staff and processes may be embedded at the recovery site. Also, when staff and processes are moved back to either the original site or a new site, the recovery site will need to be kept operational until the percentage of work done at the main premises takes over from the recovery site.

During the incident, normal management processes are necessarily bypassed or simplified, and the chain of command becomes less complex so that decisions can be made more rapidly. After the incident, normal management processes are reestablished over a period of time that is dependent on how long the recovery site has been maintained. At this point, the driving force for rapid decision making has been lost, becoming a hindrance to the recovery process. This is caused by the personnel's physiological need for order and routine and their resistance to change once the urgency and fundamental driver has been removed from the situation. This trait has been well documented by consultants dealing with change management when confronting the same issues.

Not only is this a factor in planning to move staff and processes into their new, normal premises, but it also plays a part when looking at vendors and contractors, although these are easier to manage as they are normally under contract to deliver to a company-specified site. The problems will manifest themselves when the move of some staff from the recovery site to the new site is instigated. This is because vendors will have the problem of delivering to both sites, as the recovery site must be kept open until the new, normal site can function at a level at which the work flow matches and then surpasses the work flow at the recovery site. The work flow at the recovery site decreases as the work flow at the new site increases.

A problem may arise with vendors and contractors if a contractor delivered products to the normal business premises (a single site) before the incident. During the recovery, the vendor is

Students from the University of Findlay, in Findlay, Ohio, help repair the local Java Station coffee house that was damaged by flooding downtown, September 15, 2007. Public service offices and businesses were half-emptied and lacking electricity during the severe August flooding event that swamped the upper Midwest and Plains areas. This business would use a business resumption plan to go from this state of recovery to a state of normal business, operating much as it did before the incident.

delivering to the single recovery site, but in the resumption planning period—when the recovery site needs to be kept operational while the main site is made operational—vendors may need to deliver to both sites. This would not be a problem if both sites were in close proximity, but if they are many miles apart, costs will increase and legal requirements (such as driver working hours) may come into play. The more fundamental problem is making sure the right product is delivered to the right site. Failure to do this will cause a breakdown or delay in the process, thereby causing a discontinuation of the business.

Challenges of Resumption Planning

One of the major activities where resumption planning has been unsuccessful is working out the order of processes that need to be transferred back to the main site versus transfer of whole departments. Both options have potential problems because data and information used for those processes and departments are required at both locations. Operational and even legal problems may make this impractical and must be planned for in advance—not in advance of the move, but in advance of the incident. The business continuity and emergency management professional needs to pre-plan the deconstruction and reconstruction of the business and understand that one is not the reverse of the other, especially if the disruption has been long term.

This becomes more difficult if the processes are technical or have a high level of professional competence, as a point in the process may be reached where a person with key knowledge is needed in two places at the same time, possibly miles apart. This is not a problem in the continuity or recovery phases, as there is one site in each case; however, as these processes have been deemed to be vital to the organization's survival, plans must be made for reintegration while keeping some form of customer service or processes effectively running from two sites during the resumption process. In effect, this is integrating the operations and processes that are critical to the survival of the company from both sites into one, while keeping disruption to the customer base to a minimum. As there is no longer an incident underway, both management and customers will not be as understanding as to the delay in their services. The process of moving back to the original or new site can be more difficult than the initial move to the recovery site because management and other personnel may be less motivated than at the time of the incident. Take away the incident, and for any delay or disruption to the process, management and other personnel may not be as supportive as they previously were.

Conclusion

As business resumption planning shares many of the key elements of business continuity planning, most of the work of continuity planning will be needed for resumption planning. However, a great deal of additional thinking needs to be put into the move back to the original or new site. It is always preferable to move from the recovery site back to the normal business site as soon as possible, but if this is not possible, then resumption planning must be implemented if it hasn't been done already.

Cabinet Office, UK

The Cabinet Office in the United Kingdom (UK) supports the prime minister and the government ministers by ensuring that policies and operations are developed and implemented across all government departments. It also ensures that the civil service provides effective and efficient support to government in meeting its objectives. Headed by the deputy prime minister, it contains a number of ministers who have specific responsibilities, including one who is the Minister for Civil Society.

Through its National Security Secretariat, the Cabinet Office supports the National Security Council, which is the main forum for discussing the government's objectives for national security and how it can best be delivered. Membership of the National Security Council includes the prime minister, who chairs it, deputy prime minister, chancellor of the exchequer, foreign secretary, defence secretary, home secretary, the secretaries of states for the Department for International Development and for Energy and Climate Change, the chief secretary to the treasury, and the minister for government policy. Other government ministers, the chief of the defense staff, the heads of intelligence agencies, and law enforcement officers attend as required.

The Cabinet Office advises the government on its response to cross-departmental strategic issues relating to intelligence and leads on intelligence assessment and priorities through the central intelligence machinery. As such, it coordinates the government's response to civil emergencies, terrorist incidents, and international crises.

The National Security Secretariat, a part of the Cabinet Office, prepares for and manages the coordination of the government's response to crises. It was responsible for the publication of the *Strategic Defence and Security Review: Securing Britain in an Age of Uncertainty*.

Another part of the Cabinet Office is responsible for cyber security. The Office of Cyber Security and Information Assurance (OCSIA) supports ministers within the Cabinet Office and the National Security Council in determining priorities in relation to securing cyberspace. A new Cyber Security Strategy, which sets out how the UK will support economic prosperity, protect national security, and safeguard the public's way of life by building a more trusted and resilient digital environment, was published in November 2011.

Until the end of the last century, the UK was still using civil defense legislation to operate its emergency and crisis management systems. However, the Y2K threat, some serious flooding, and a fuel blockade at the turn of the century led to transferring responsibility for emergency management from the Home Office to the Cabinet Office and the setting up of the Civil Contingencies

Secretariat (CCS) in July 2001. This, in turn, led to the introduction of the Civil Contingencies Act in 2004, which provides a single framework for managing emergencies.

As a part of the Cabinet Office, the function of the CCS is to support ministers in developing policy relating to emergencies, thus ensuring that the government and key stakeholders continue to function and deliver public services during a crisis. This is achieved by working with government departments; the devolved administrations in Scotland, Wales, and Northern Ireland; and key stakeholders toward ensuring that plans, procedures, and systems are in place to cover the full range of disruptive challenges that have been identified.

The work of the Secretariat is carried out by four groups. The Capabilities Team manages the cross-government Capabilities Programme and provides secretarial support to the cabinet committees responsible for driving the program forward. Working with other government departments, the Local Response Capability Team ensures that the requirements of the Civil Contingencies Act 2004 are implemented, and it manages three capability workstreams: local response, community resilience, and recovery. The International Team is responsible for liaising with European Union and North Atlantic Treaty Organization partners to ensure that UK policy on civil protection activity is coordinated. The Exercise and Operations Team has two functions. It leads on policy relating to exercises and is responsible for the coordination of a government-wide exercise program, and, in the event of a crisis, it looks after CCS interests during the response to that crisis.

The Emergency Planning College, a part of the CCS, is the UK's leading emergency planning and crisis management training center. The aim of the college is to develop the key skills and awareness required to improve the capability of all levels of government, together with the public, private, and voluntary sectors necessary to prepare for, respond to, and recover from potential crises.

When a crisis occurs in the UK, the committee set up to deal with it is often referred to as COBR or COBRA. This is a term coined by the media; it is not officially recognized by the government or emergency responders. The former merely stands for the Cabinet Office Briefing Room, that is, the room in which the committee meets, the latter for Cabinet Office Briefing Room A, because the meeting used to be held in Conference Room A within the Cabinet Office.

Carrying Capacity

Carrying capacity can be defined simply as the ability of a given environment to sustain the current and anticipated utilization of its resources in a sustainable manner without deterioration. For example, carrying capacity in the context of the natural environment is the ability of the ecosystem to sustain a certain population of animals without degradation of pasture, water, and habitat. Looking at the issue from the perspective of human societies, it is generally believed that Earth has only a certain carrying capacity to support the resource needs of the populations, beyond which the environment will deteriorate and resources will be depleted, thus irreversibly and negatively affecting populations.

This article examines the theoretical and practical dimensions in regard to carrying capacity, examples of different resources, ways in which carrying capacity can be interpreted, measures of carrying capacity, and relationships between carrying capacity and disasters.

Considering the issue at a more practical and tangible scale, carrying capacity of localized systems such as a piece of pasture land, a city, or a river can be stretched beyond a maximum limit, resulting in disasters. For example, the pasture can be overgrazed by increasing numbers of livestock herds, leading to depletion of grass, which then leads to death of animals, which leads to starvation, malnutrition, and death of human populations sustained on this land. Similarly, riverbeds can be used for construction of houses, growing crops, and so forth, and during flooding these are devastated, resulting in death of populations. In an overcrowded city (an urban ecosystem), a fire hazard can easily cause a major disaster as people cannot run away or protect assets, or a disease outbreak can spread easily, leading to mass morbidity and mortality.

Carrying capacity needs to be understood from a range of interactions and interrelationships. The most important are the relation between supply and demand for resources, between populations that share the resources and cooperation/competition between them for the resources, and management actions (policies, laws) preserving/conserving resources for the future and the overwhelming need of the current generation.

This article discusses some of the factors and human actions that are known to be negatively affecting and reducing the carrying capacity of different ecosystems and their impact on the ecosystem, including disasters. Examples of three resources—water, land, and forest—are provided below, including the way human populations benefit from them and the actions that degrade these resources and their impact.

Water, Land, and Forest Resources

Water resources include groundwater and surface water in oceans, rivers, and glaciers. Water is a critical resource for survival by supporting food, commerce, energy, and several production systems. Key concerns include overutilization of the resource beyond the ability of the system to recharge, and pollution by dumping domestic, industrial, and toxic wastes. Dams created on rivers for hydroelectric and irrigation systems are also noted to accentuate flooding in the catchment areas. Critical impacts include scarcity and depletion (especially groundwater), leading to loss of food production, spread of communicable diseases, and severe conflict over the resources among populations. Sustainable water management is a growing body of knowledge and practice meant to conserve and preserve water resources. Pollution control initiatives across large river systems have been tried around the world with great success. Micro water harvesting structures have been identified as a feasible alternative to large dams for irrigation and present minimal or less environmental impacts. Recycling and reuse of water is another strategy that is being increasingly used in industries, municipalities, and offices as well as in individual homes.

Land is a resource for agriculture, human settlements, industries, and many other livelihood systems. Key concerns include degradation from excessive use (e.g., depletion of the productive surface soil), use of chemicals in agriculture systems, dumping of wastes, and overcrowding (especially in cities). Impacts include reduced agriculture production and conflicts between communities. Several strategies for integrated land management have been developed globally in order to better achieve sustainable land use practices. These include national government policies regulating land use patterns, urban zone planning, proper disposal of hazardous waste, land reclamation programs in degraded areas, and reduction of soil loss through tree planting and increasing vegetative cover.

Forest resources provide timber for housing; sustain animal and bird populations that also provide food for gathering communities (e.g., tribal populations); support sustaining atmospheric regulation and rain, working as a carbon dioxide sink and supporting watersheds; and offer recreational opportunities (including tourism). Massive deforestation in order to meet increasing resource demands of growing populations and conversion of forest land to other uses such as industry and mining, agriculture, and housing are resulting in drastic reduction in forest cover, leading to fluctuation in global atmospheric processes and climate change, loss of species, and shrinking of tribal populations. Lack of forest cover also leads to denudation of soil cover. The issues involving forest resource degradation have been identified as a critical element within environmental conservation and preservation policies worldwide. A range of interventions and strategies have been put in place, including laws against tree cutting, policies on use of forest land, and development of alternatives for timber (e.g., use of concrete poles instead of timber in railway tracks, high-density plastic slabs used in house construction instead of timber).

Principles

Carrying capacity can be explained through the following principles:

Carrying capacity of a system can change. With the invention of new technologies, finding of alternative resources and technologies, and changes in resource use patterns, carrying capacity of a given system can go beyond what it could have otherwise supported. Renewable energy sources such as solar, wind, and nuclear have helped populations reduce dependence on fossil fuels, thereby creating opportunities for human populations to expand in otherwise inhospitable areas, increase energy use, and create better living conditions. At the same time, carrying capacity of a system can also reduce with dependence on factors that hasten to degrade resources. Oil spills in the ocean are one such example, wherein the entire fish and aquatic life can die out. Large forest fires can decimate hundreds of thousands of hectares of pristine forest land. Extinction of dinosaurs is widely believed to have been caused by meteorite hits on Earth.

Carrying capacity is also a function of time. This is linked to resource utilization (or misutilization) over a period of time by a given population. It is simple to assume that all other factors being constant, more time spent will lead to increasing utilization of resources by a population. This is especially true for fossil fuels, which take millions of years to be produced and do not regenerate. Similarly, more time spent can also mean opportunity for creation/invention of alternate resources and regeneration of depleted resources (e.g., forest and grassland growth).

Spread effects in regard to carrying capacity. Interrelationship between different levels and types of ecosystems means that an adverse or positive impact on one ecosystem can also affect other ecosystems surrounding it. For example, heavy pollution load on a landmass (industrial waste disposal) can mean contamination of the groundwater as well as pollution of the nearby river system. Similarly, conservation efforts in a forest area (plantation, stopping tree cutting) can

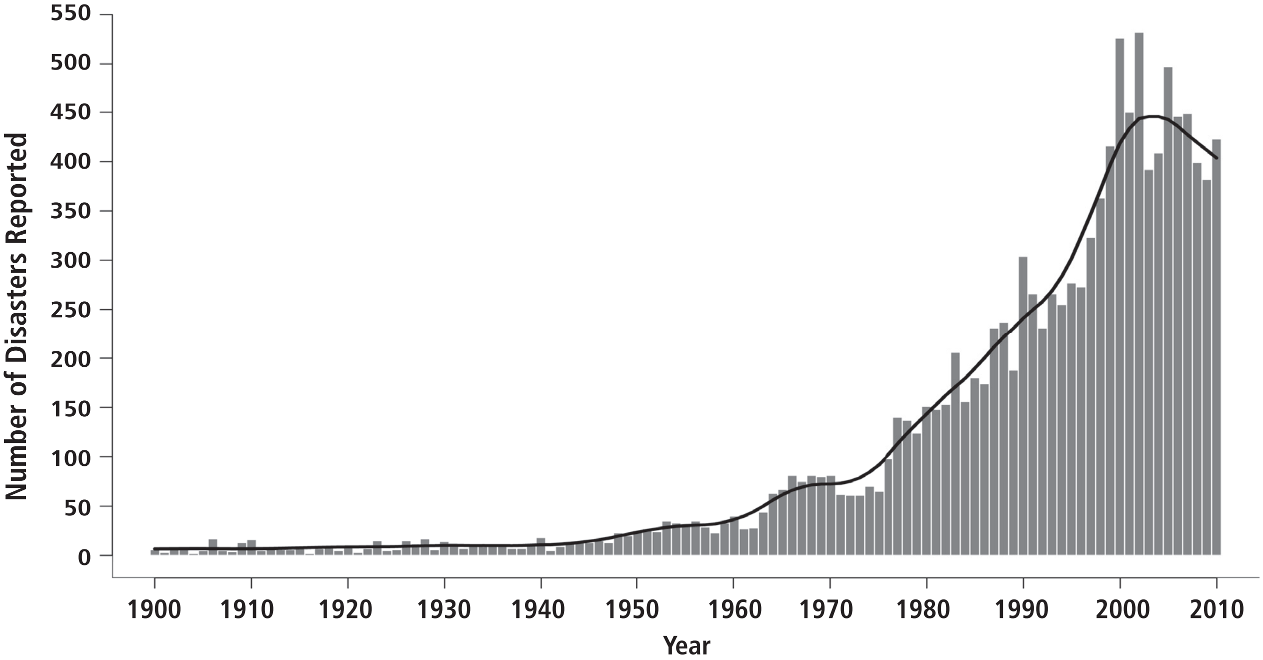

Figure 1 Natural disasters reported, 1900 to 2010
Source: International Disaster Database (EM-DAT).

mean better recharge of the groundwater and increased wildlife population.

The impact can also cascade through the ecosystem upward or downward. For example, contamination of small rivers and rivulets feeding into a larger river or lake can mean pollution of the latter, thereby reducing carrying capacity (death of fish and aquatic flora and fauna, algal bloom, etc.).

Carrying capacity can be explained at various scales. For example, we can research and talk about the carrying capacity of an entire ocean and, at the same time, look at the carrying capacity of individual small islands within these oceans.

How to Calculate Carrying Capacity

Calculating carrying capacity is difficult and complex given the dynamic nature of elements that determine carrying capacity. Some of the factors that need to be taken into consideration when determining carrying capacity are as follows. Quantification of all the factors below is probably impractical, and therefore a great deal of subjectivity, extrapolation, and interpretation need to be used in developing understanding of carrying capacity:

- Population size: current population, rate of growth, migration (in and out), fluctuations
- Knowledge and understanding of the resources: relationships between them, and support thresholds
- Seasonality and time frame: fluctuation of resources during the year and over a period of time
- Social factors: types of uses, ethical practices in resource use and sharing/competition between populations, legal frameworks, overdependence on some resources over others
- Technological factors: understanding of resources available, development of alternatives, options available
- Economic factors: cost for use of resources, trade relations between countries regarding resource sharing
- External factors: disasters, diseases, and other extreme events such as weather and climate changes

Carrying Capacity and Human Populations

Human activities are causing significant environmental impact at a wider level and thereby stretching the carrying capacity of the surrounding ecosystems and the Earth's ecosystem as a whole. Climate change, global warming, deforestation, and global sea level rise and flooding of low-lying areas, due to increasing industrialization, the load of toxic gases on the atmosphere, and increasing global population, are some of the biggest challenges facing world populations. Links are being established between these issues and increased frequency of natural disasters such as flooding, landslides, and drought as well as conflict between communities over scarce resources (e.g., conflict between north and south Sudan, conflict between pastoralist communities in several east African countries such as Ethiopia, Kenya, and Uganda).

Figure 1 provides a summary from the International Disaster Database of disaster trends from 1900 to 2010, indicating the increasing risk to populations and economies. There has been growing recognition of the need to address the above challenges, thereby not overstretching the carrying capacity for current and future generations.

Several international conventions, frameworks, and coordination structures have been developed in order to address issues of climate change, sustainable development, and disaster risk reduction. Some of the key stakeholders bringing together a range of global actors are as follows:

- United Nations Framework Convention on Climate Change, Kyoto Protocol (http://unfccc.int/2860.php)
- United Nations International Strategy for Disaster Reduction (http://www.unisdr.org)
- Hyogo Framework for Action (2010–2015): Building the Resilience of Nations and Communities to Disasters (http://www.unisdr.org/we/coordinate/hfa)
- Rio +20-United Nations Conference on Sustainable Development (http://www.unisdr.org/2012/rioplus20)

Cascading Crisis

A cascading crisis is an unexpected event, or series of events, that creates a damaging domino effect of failures within or across systems. Although some cascading crises seem to stem from a single trigger event, others are created by the compounding of multiple interaction effects. The waves of ensuing failures result from the growing complexity and increasing interdependence of society. Global markets, increased mobility, and advanced technology have led to a complex network of social, corporate, industrial, financial, technical, infrastructural, and administrative systems. What once would have been classified as a localized crisis can have reverberating effects across these increasingly dynamic and interdependent systems. A cascading crisis can impact multiple industries and jurisdictions across geographic boundaries (local, regional, national, international), policy and societal sectors (environmental, health, economic, foreign policy), and critical infrastructures (energy, banking and finance, transportation, human services, telecommunications). The complexity of internetwork reliance creates systematic vulnerabilities prime for a cascading crisis.

Cascading crises often go beyond the conceivable scope of crisis management planning. Crisis management concentrates primarily on risks within an entity’s locus of control. Localized risks are more common, and predetermined strategies can be enacted quickly to mitigate the crisis. Crisis managers also develop strategies that can be enacted to limit the effects of crises beyond the entity’s locus of control. For example, an organization cannot control whether it is hit by a tornado, but it can control how warnings are communicated to onsite stakeholders, identification of safe shelters, plans for resuming operations if the primary location is damaged, and development of policies for employee leave to help with cleanup if other areas of the community are damaged. Because a cascading crisis can be caused by a multitude of factors beyond the control of a crisis manager, identifying vulnerabilities and predetermining strategies to address cascading crises is challenging. Three core areas of crisis management research lend to our understanding of cascading crises: normal accident theory, chaos theory, and transboundary crisis.

Cascading Crisis as Normal Accident

Normal accident theory provides insight as to why cascading crises occur. Normal accident theory describes the ways in which normal, routine failure may lead to catastrophic crises through the interactive complexity that develops around larger-scale sociotechnical systems. As systems become technologically intense, they increase in complexity and interactivity, creating tightly coupled systems. Tight coupling occurs when initial failures can rapidly bring down other parts of a system because there is little to no slack or buffer between the parts. Thus, crisis managers do not have the time or ability to make corrections before failures affect interrelated parts or other systems.

Even on a small scale, cascading crises can have broad impacts across industries. For example, the modern food production system has become increasingly complex and susceptible to systemic breakdowns. The 2008–09 salmonella outbreak in processed peanut products was caused by contamination in two plants owned by one company supplying less than 2 percent of peanut products in the United States. And yet, because Peanut

Corporation of America (PCA) was an intermediary processor that sold ingredients to other companies, more than 3,900 products including snack crackers, granola bars, cookies, and ice cream from more than 200 companies were recalled. Jarred peanut butter, while unaffected by the recall and unrelated to PCA's processing, also experienced a sharp sales decline. Poor crisis management by a company that supplied less than 2 percent of all peanut products and a reliance on supplier testing systems sickened 714 people, contributed to nine deaths, and cost the peanut industry an estimated $1 billion. In a cascading crisis, organizations cannot control how the actions of another entity will ultimately affect the bottom line. Directly affected organizations that purchased peanut products from PCA should have prepared for how a failure in the supply chain could manifest into a crisis. However, jarred peanut butter companies had no locus of control over the sanitation of PCA or the quality of the products it shipped and no way to silence the cascading crisis that echoed through the peanut industry.

Cascading Crisis as Chaos

Chaos theory provides additional insight into understanding cascading crises by emphasizing the complexity, nonlinearity, and lack of simple predictability associated with complex systems. When systems reach high levels of complexity and nonlinearity, enacted through interdependent networks, cascading crises are inevitable. The bifurcation point, or trigger event, is difficult to identify because so many fractals interact to create the cascading crisis. Chaos theory suggests that self-organization will ultimately occur as strange attractors come together to bring the spiral under control; however, the new system creates a higher level of order and another level of complexity that can contain the damage or produce more drastic effects at a later date. The 2008 nationalization of Fannie Mae and Freddie Mac to mitigate the mortgage crisis in the United States and the European Union's 2012 bailout plan for Greece and Portugal to save the euro are examples.

The root of a cascading crisis in the financial sector is difficult to identify. In 2007, as the housing bubble in the United States began to deflate and subprime mortgage losses accumulated, little was done to prevent the inevitable fall of banking giants until the entire financial industry was facing either bailout or bankruptcy. The challenge in understanding cascading crises is that there is not always a single identifiable trigger event or tipping point that starts the domino slide. The butterfly effect described in chaos theory provides the metaphor for how small variances in a system can cause much larger impacts. Potentially innocuous changes in mortgage lending options, oil prices, and tax policies can lead to devastating effects on a much larger scale.

Although one trigger event may be difficult to identify, debt crises do provide a clear example for how an industry can become so interdependent. Subprime buyers were able to take out high-risk loans from local banks. Those banks sold the loans to larger banks, which sold the loans to even larger banks, which sold the loans to mortgage giants and financial investment banks, which ultimately had to get loans from the U.S. government to avoid bankruptcy. Once the crisis was triggered, strategies had to be determined for how to contain the damage as it rippled through the financial sector.

Cascading Crisis as Transboundary

Cascading crises are often transboundary, crossing political, functional, and temporal boundaries. Political boundaries are commonly crossed in national disasters that overwhelm local government. Unfortunately, when assistance is requested from state, national, or international governments, the response can become more complex rather than more efficient, as was found in the response to Hurricane Katrina in 2005. Cascading crises can also cross functional boundaries threatening multiple infrastructures, such as the mortgage crisis tightening credit lines for automakers who also received bailout loans from the U.S. government. Finally, while some crises have a defined timeline, others transcend temporal boundaries. For example, the Chernobyl disaster was triggered in 1986, but the lasting health effects can still be seen today as elevated cancer cases continue to be reported in areas contaminated by the nuclear fallout. If a crisis is transboundary, it may not even be recognized as a potential risk by the affected entities. This is why cascading crises can escalate so rapidly. By the time entities recognize how they could be impacted by a cascading crisis, they are often already feeling the effects.

The March 11, 2011, earthquake along the northeast coast of the Tohoku region of Japan provides a devastating example of a transboundary cascading crisis. The 9.0 earthquake—the largest ever recorded to have hit Japan—generated a wall of water that swept away homes, businesses, and almost 20,000 lives. The waves from the tsunami also triggered meltdowns of three reactors at the Fukushima Daiichi nuclear power plant, releasing radioactive material and forcing the evacuation of about 90,000 people from their homes. The compounding natural disasters and technical disaster crossed political, functional, and temporal boundaries, and the cascading effects could be seen around the world.

The quake was felt hundreds of miles from the epicenter, but the tsunami caused the most destruction as it swept over the political boundaries of hundreds of cities and dozens of prefectures. Local, regional, and national response efforts were quickly overwhelmed, and aid from the international community had to be coordinated. Political boundaries were also crossed as nuclear agencies and experts from around the world were brought in to assist the Tokyo Electric Power Company (TEPCO) in containing the radiation emitting from the damaged nuclear reactors. The plant was eventually shut down in December 2011, but the crisis continued to spread throughout the nuclear industry. A year after the disaster, all but two of Japan's 54 commercial nuclear reactors had been taken off-line until safety could be assured. Germany halted its nuclear power industry, and the U.S. plans to renew investment in nuclear power stalled. A tsunami, caused by an earthquake, triggered the technical failures at Fukushima Daiichi nuclear power plant, but the effects reverberated across the energy sector as reliance on domestic and foreign fossil fuels increased.

Both the immediate effects of the earthquake and tsunami and the ensuing energy failures crossed functional boundaries. The Tokyo Stock Exchange plunged in the week following the earthquake, taking shares of Toyota, Nissan, Sony, and Panasonic to devastating low prices. Japan's manufacturing sector was hit particularly hard as property damage and workforce displacement created shortages for automakers, technology firms, and several other industries. As a major supplier of technical equipment parts, Japan's shortages left manufacturers using just-in-time strategies around the world without parts in the weeks and months following the crisis. The energy crisis created additional backlogs in the supply chain. Before the crisis, nearly a third of Japan's electricity came from atomic energy. Rolling blackouts and brownouts to conserve energy limited recovery as production was curbed by power shortages.

The crisis also crossed temporal boundaries. Thousands of people lost their lives in the immediacy of the earthquake and tsunami, and hundreds of thousands were still without homes a year later. Across functional boundaries, the tourism industry dropped nearly 60 percent in the months following the earthquake. A year later, the industry had almost fully recovered. Meanwhile, the agricultural industry will continue to be impacted by the nuclear fallout for years to come. Once prosperous farmland in the Fukushima Prefecture now only grows toxic crops farmers cannot sell and are too afraid to eat. Lasting health effects from the radiation absorbed over time will take decades to materialize in the form of increased cancer cases in the communities surrounding the power plant. The 2011 Japan earthquake, tsunami, and nuclear disaster is a prime example of a cascading crisis.

According to normal accident theory, cascading crises will only increase in frequency and severity as technology advances and systems and societies become more interconnected. Identifying vulnerabilities to cascading crises will continue to challenge crisis managers, but expanding the scope of crisis management planning to incorporate additional slack and contingency plans can limit the effects of cascading crises.

Catastrophe, Definition of

In the disasters literature there is controversy about whether the term *catastrophe* can be differentiated from *disaster* or whether they are synonyms. The word *catastrophe*, which first appeared in the English language in the 1500s, comes from the ancient Greek word *katastrophe*, meaning “overturning” or “sudden turn,” and its Latin derivative *catastropha*. It denotes a moment of sudden cataclysm, in which things change inexorably. Setting aside exaggeration and hyperbole, a catastrophe can be considered to be an unusually large disaster.

In functional terms, a catastrophe can be differentiated from a disaster in the needs and responses it generates (see Table 1). It is likely to overwhelm the capacity to respond of the local area that it affects. It may also overwhelm regional capacity and demand a national or international response. For example, the Haiti earthquake of January 12, 2010, killed at least 230,000 people and, because Haiti is the poorest country in the Western Hemisphere and was quite unable to cope, it elicited a response from 129 nations. Catastrophic disasters almost always result in an international appeal for aid and assistance. Commonly, about 70 nations may respond by sending cash, relief goods, or personnel. The exceptional impact, suffering, and international response involved in the Haiti earthquake surely qualifies it to be regarded as a catastrophe, hence a disaster of exceptional magnitude and impact.

There have been numerous attempts to quantify the thresholds at which events become disasters. For instance, the EM-DAT database of the Centre for Research on the Epidemiology of Disasters at the Catholic University of Louvain in Belgium defines disaster as involving 10 or more deaths and 100 or more people affected, and requiring a declaration of a state of emergency or a call for international assistance. Although it is sometimes necessary to come up with a means of differentiating or classifying such events, disasters are sufficiently complex events to defy efforts to constrain them to specific thresholds, and that is even truer of catastrophic disasters. In other words, such events are in some way exceptional, but what defines “exceptional” is open to many different interpretations.

The advent of the 3rd millennium gave rise to some ill-conceived predictions of global catastrophe, but it did redress the balance after two centuries in which the doctrine of uniformitarianism had the upper hand over catastrophism. The latter advocates large, violent events as the source of global changes, while the former theory argues for gentle, continuous processes as the main source of developments. In reality, both the physical and the social evolution of the world are functions of both catastrophic and continuous processes and are complex enough for it to be very difficult to discern which of these is the more important. Moreover, catastrophic events, such as major volcanic eruptions, that can have a significant impact on global climate or social processes are very rare and hence cannot adequately be evaluated statistically.

Nonetheless, events have occurred that show how the interlinking of phenomena can increase the potential for catastrophe. The Great Eastern Japan (or Tohoku) Earthquake and Tsunami of March 11, 2011, involved a magnitude 9.0

Case Study: Events That Have Shaped the Definition of Disaster

The Indian Ocean tsunami of December 26, 2004, affected 12 countries over a vast area of Asia and Africa, killed about 230,000 people, injured 125,000, and displaced 1.69 million. It was generated by one of the 10 strongest earthquakes in recorded history, with an estimated magnitude of 9.1–9.3. It thus fulfills any reasonable definition of a catastrophe. However, one might say the same of some rather smaller events. Hurricane Mitch, which struck eight Caribbean and Central American countries in late October 1998, killed 11,000 people, many fewer than the Haitian earthquake, yet it is reckoned to have set back economic development in some parts of the region (notably in areas of Honduras and Nicaragua) by 20 years. If it were not something of a contradiction in terms, one might call Mitch a "catastrophe at the local level." In this sense the occurrence of catastrophe is in direct relation to the sum total of human suffering generated, but this is not easily measured or even adequately conceivable in robust scientific terms. Nor is it uniform even within a single disaster.

A woman searches in the rain through debris where her house once stood in Banda Aceh, Sumatra, Indonesia, in January 2005. The December 26 catastrophic earthquake and tsunami affected 12 countries in Asia and Africa, killing about 230,000 people.

earthquake, a maximum wave height of almost 39 meters, and widespread contamination by radioisotopes emitted from the damaged Fukushima nuclear power plant. This was obviously an exceptional event and, with 19,500 deaths, well within the bounds of catastrophe. But both natural events and human-induced catastrophe (particularly that which involves nuclear fission) could cause significantly worse events, perhaps orders of magnitude larger. Moreover, very high death tolls are forecast for future earthquakes in cities such as Istanbul and Tehran, again diagnostic of the potential for catastrophe.

Two Further Interpretations

Two other interpretations of the term *catastrophe* deserve mention. Both are hardly compatible with the matters discussed above. First, catastrophe theory is a subset of the branch of mathematics known as bifurcation theory and a special case of singularity theory in geometry. In this, small changes in a nonlinear system can cause abrupt changes in system state or behavior, the so-called catastrophes, of which eight different models have been identified. Despite the name, little is inherently catastrophic about the theory, and its utility for modeling catastrophic situations is severely limited. The higher-order singularities are too abstruse to model the trajectories of relevant variables in real life. The lower-order bifurcations do little to improve models based on simple abrupt changes of state. Hence, after a burst of enthusiasm in the 1960s and 1970s, the theory has relapsed to the status of an elegant but neglected mathematical formulation.

Second, in insurance circles the term *catastrophe* is more widely and loosely employed than it is in science. Catastrophe insurance refers to

Table 1 Differentiation of size of event by process and impact

	Incidents	Major incidents	Disasters	Catastrophes
Impact	Very localized	Generally localized	Widespread and severe	Extremely large
Response	Local efforts	Some mutual assistance	Intergovernmental response	Major international response
Plans and procedures	Standard operating procedures	Emergency plans activated	Emergency plans fully activated	Plans potentially overwhelmed
Resources	Local resources	Some outside assistance	Interregional transfer of resources	Local resources overwhelmed
Public involvement	Very little involvement	Mainly not involved	Public very involved	Extensively involved
Recovery	Very few challenges	Few challenges	Major challenges	Massive challenges

Source: Based on Tierney, Kathleen. "Hurricane Katrina: Catastrophic Impacts and Alarming Lessons." In *Risking House and Home: Disasters, Cities, Public Policy,* J. M. Quigley and L. M. Rosenthal, eds. Berkeley, CA: Institute of Governmental Studies, Berkeley Public Policy Press, 2008.

protection against damage and losses caused by natural disasters, such as earthquakes, floods, and hurricanes. It is by no means universal nor entirely effective at cushioning losses. The term *catastrophe* here implies a differentiation between payments that result from single losses (a house that burns down, wind or water damage to an individual building, etc.) and collective losses in which insurance companies must pay out to many policyholders. In general terms, catastrophe insurance is controversial because it can involve unusually large risks of insolvency and because there are problems of raising enough capital to cover the risks.

Conclusion

Sociologist Enrico L. Quarantelli wrote "What Is a Disaster?" for the November 1995 issue of the *International Journal of Mass Emergencies and Disasters*. He noted, "… to be concerned about what is meant by the term *disaster* is not to engage in some useless or pointless academic exercise. It is instead to focus in a fundamental way on what should be considered important and significant. …" The same is true of the term *catastrophe*, although in both cases the controversies about meanings are unlikely to be resolved, even by very well-informed debate.

Catholic Relief Services

Catholic Relief Services (CRS) is an international nonprofit organization that provides support for survivors in all crisis phases, from mitigation to recovery. This brief introduction discusses the history and contemporary characteristics of CRS, the philosophy of the organization, and its crisis management practices.

Organization

Initiated in 1943 by the Roman Catholic bishops of the United States to serve war refugees in Europe, Catholic Relief Services continues to focus on the poor internationally. Although a Catholic organization, CRS serves those in need no matter a person's race, nationality, or creed. The organization has traditionally focused on crisis relief and mitigation, though by the 1960s it had moved into sustainable community development efforts and capacity building strategies for broader civil society. The most recent statistics illustrate the continued activities of Catholic Relief Services. Based in Baltimore, Maryland, CRS has an annual budget of $823 million (fiscal year 2010), approximately 5,000 employees worldwide, and tens of thousands of volunteers. It assists more than 100 million people annually in nearly 100 countries.

In addition, CRS belongs to a much broader international coalition, Caritas International. Caritas, with 165 organizations in more than 200 countries, is one of the largest networks worldwide aimed at reducing poverty and injustice. This connection enables CRS to significantly scale up its support capacity during and after a crisis.

Governing Philosophy

CRS bases its crisis management on its 60 years of experience and Catholic social teaching. Some of the guiding principles most relevant to emergencies include subsidiarity (focus on grassroots level decision making and development), solidarity (all people play a role in mitigating crises), and the option for the poor (the most vulnerable must be considered when decisions are made).

A recent example of this was CRS' involvement in Haiti after the 2010 earthquake. The immediate response was the provision of food, water, shelter, and sanitation to survivors. Once the immediate threat had passed, the organization transitioned to helping individuals return to their neighborhoods with a 30-month, $38-million Community Resettlement and Recovery Program. The project will potentially assist 25,000 families to return to their communities with integrated shelter, water and sanitation, infrastructure, protection, and livelihoods solutions.

Crisis management, however, is only one of 12 different ways CRS serves the global community. With the goal of addressing issues ranging from agriculture to HIV/AIDS and public policy to education, this diversity is also reflected in the manner in which CRS approaches crises. The organization views emergencies as a symptom of larger problems, and therefore any disaster relief or recovery must be implemented alongside other development strategies. As is noted in its mission statement, the organization's goal is to "promote human development by responding to major emergencies, fighting disease and poverty, and nurturing peaceful and just societies."

Crisis Management Practices

As noted above, CRS approaches crises with a holistic vision. This vision, defined by 18 principles, fits under four general themes: focus on vulnerable populations, work with local actors, increase capacity throughout the process, and create capacities that will last beyond the intervention of the organization.

First, CRS bases programming strategies and decisions on the needs of affected populations, doing so in a timely manner. In particular, the organization targets assistance toward the most vulnerable populations; specifically, the aim is to serve marginalized social identities such as the poor, women, and children.

Second, CRS involves community members and leaders. The organization makes it a point to ensure a legitimate representation of target population input within the planning, implementation, and evaluation of activities. Additionally, CRS attempts to build upon the strengths of local partners and to develop their capacity to mitigate and respond to emergencies, while also integrating peace-building approaches and reducing intergroup tensions.

Third, Catholic Relief Services takes a critical tack toward crisis management. The organization uses a Catholic social justice approach, implementing strategies based on its assessment of justice issues. Similarly, while CRS does address the immediate problems after a disaster, it furthers its work by also assessing the root causes of the human vulnerability that turned a hazard into a disaster. This is illustrated by its long-term commitment to various projects and nations; in Haiti, for example, the organization has been working since 1954 implementing disaster response, health, safety net (grassroots development programs), and, more recently, HIV/AIDS programs.

Finally, CRS has clear guidelines that structure and inform its management efforts. CRS states that organizational management programs should coordinate with other agencies, follow the emergency planning cycle, and be designed with an explicit exit strategy in order to prevent dependency. In addition, all programs should demonstrate technical expertise and measurable indicators of positive results. Combined, these four themes outline the core principles that define CRS crisis management practices.

In sum, Catholic Relief Services, under the banner of Caritas International, is one of the largest religious organizations to work with crisis management. Its global reach and religious roots provide a strong foundation for the long-term participation of the organization in all aspects of crisis management.

Centers for Disease Control and Prevention (CDC)

The Centers for Disease Control and Prevention (CDC) focus on practical, applied, and academic research and supporting public health activities in the United States. The CDC is housed in the U.S. Department of Health and Human Services. The CDC comprises over 15,000 employees in 168 different occupation classes, working in over 50 countries. The majority of employees work at the CDC headquarters in Atlanta, Georgia.

History

On July 1, 1946, the Communicable Disease Center (CDC) was started in Atlanta, Georgia, as an extension of the Malaria Control in War Areas (MCWA) agency from World War II. The MCWA's and the CDC's primary focus was eradicating malaria. The occupational classes were predominantly entomologists and engineers, with a few medical doctors. In 1948, the CDC was recognized worldwide for its enterobacteriaceae pathogens classification (i.e., *E. coli*, salmonella, and *Yersinia pestis*). In 1951, the Epidemic Intelligence Service was formed to protect citizens against human-made epidemics and living weapons (biological) warfare. In 1958, for the first time, a CDC team traveled overseas to investigate a southeast Asia smallpox and cholera epidemic. The first CDC "biocontainment lab" was constructed in 1969. In 1970, the name of the CDC was officially changed to the Center for Disease Control; in 1981, Center became Centers; and the words *and Prevention* were added in 1992. In 1976, the CDC investigated a new lethal hemorrhagic fever in Zaire and Sudan, which later became known as Ebola. The *Morbidity and Mortality Weekly Report* (*MMWR*) on June 5, 1981, described the first case of what would become known as AIDS (acquired immune deficiency syndrome). In 1993, the CDC investigated a vector-borne disease (e.g., rodents) in the southwestern United States that became known as hantavirus. On July 1, 2011, the CDC celebrated its 65th anniversary.

Organization of the CDC

The CDC as an organization comprises the Office of the Director (administrative), the National

Institute for Occupational Safety and Health (NIOSH), and the Center for Global Health. The NIOSH investigates and prevents workplace-related illnesses and injuries. The Center for Global Health is focused on managing and coordinating public health issues of infectious diseases, noncommunicable diseases, public health emergencies, refugee health, and addressing and reducing injuries around the world. There are also five offices of the CDC: (1) Infectious Diseases; (2) Non-Communicable Diseases, Injury, and Environmental Health; (3) Public Health Preparedness and Response; (4) State, Tribal, Local, and Territorial Support; and (5) Surveillance, Epidemiology, and Laboratory Services. Under each of these offices are a number of specialized divisions and departments.

Public Health Preparedness and Response

All CDC offices focus on crisis management and emergency/disaster preparedness. The coordinating body is the Office of Public Health Preparedness and Response (PHPR; formerly known as the Coordinating Office for Terrorism Preparedness and Emergency Response). The PHPR manages, prepares, and supports (monetary and nonmonetary) activities addressing terrorism and emergencies across international, federal, state, and local public health offices. Under the PHPR are several divisions and offices, such as the Division of State and Local Readiness (DSLR), the Division of Strategic National Stockpile (DSNS), the Division of Emergency Operations (DEO), the Division of Select Agents and Toxins (DSAT), and the Office of the Director (OD). Each of these divisions plays a supportive role in crisis management and emergency/disaster preparedness.

The DSLR is responsible for managing and coordinating Public Health Emergency Preparedness (PHEP) cooperative agreements that provide funding to state and local public health in emergency preparedness and response efforts. The PHEP works in the National Incident Management System (NIMS) framework in conjunction with state and local response efforts. The DSNS is responsible for the Strategic National Stockpile (SNS), which is a national repository for antibiotics (oral and IV), vaccines, airway equipment (i.e., oral airway, endotracheal tubes, and bag valve masks), ventilators, serum containing antitoxins, chemical antidotes, IV administration, and medical/surgical supplies. The SNS is made available in emergencies and when public health response efforts at the state and local levels are overwhelmed. The DSNS provides technical assistance to state and local jurisdictions. The DSNS also coordinates the delivery, storage, distribution, and dispensing of the SNS pharmaceutical, vaccines, and medical resources at the federal, state, and local levels.

The DEO is responsible for the CDC emergency public health management efforts of preparedness, assessment, response, recovery, and evaluation. Like other emergency management groups, the DEO is in operation before, during, and after a public health emergency. The DEO operates the CDC's Emergency Operations Center (EOC) and develops response plans, conducts training and regular exercises, and performs after-action reports. The CDC EOC is a slight variation of NIMS EOC because it is focused on public health, such as acts of terrorism (i.e., dirty bombs) and noncommunicable and infectious disease outbreaks. The CDC EOC is staffed 24 hours a day, can staff up to 230 people during an emergency, and is able to deploy medications, collect samples and specimens, and transport expert staff to anyplace on the planet. Deployment for domestic issues occurs within two hours after notification and in six hours for international emergencies.

Another program of the PHRP is the Division of Select Agents and Toxins (DSAT), which operates the Select Agent Program. The DSAT promotes laboratory safety and security through inspection and enforcement of special agent regulations, including the possession, use, and transport of toxins (called special agents) and biological agents that pose a serious threat to public health. The CDC works with the U.S. Department of Justice, Criminal Justice Information Services Division (CJIS), to aid in regulation, compliance, and enforcement. The CJIS approves individuals/groups requiring access to select agents and performs security risk investigations. DSAT also works in conjunction with the U.S. Department of Agriculture agency called the Animal and Plant Health Inspection Service (APHIS) to regulate the possession, use, and transport of special and biological agents that are a serious threat to plant and/or animal populations or products.

The Office of the Director (OD) is the administrative body of the CDC. Among many other administrative activities, the OD runs the Career Epidemiology Field Officer Program, which utilizes PHEP funds to recruit, train, and develop epidemiologists for state and local public health departments. The OD also oversees the Preparedness and Emergency Response Learning Centers, which is a network of higher education departments throughout the United States that prepares the public health workforce.

Chaos Theory

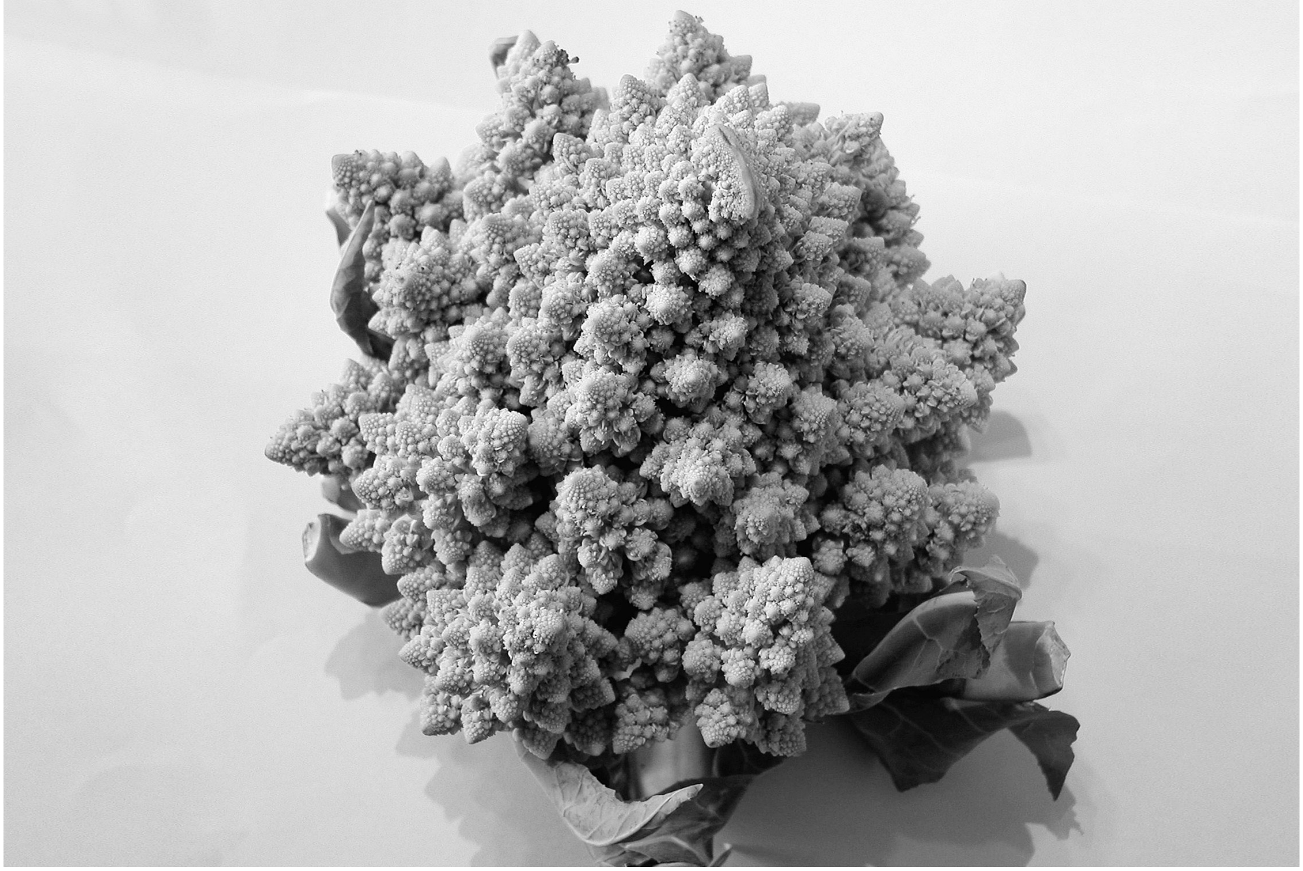
Chaos theory recognizes there is a natural tension between order and disorder. Where one expects to find order, one find chaos, and where one expects to find chaos, one finds order. Chaos theory is an extension of systems theory; however, it adds a fundamental paradigmatic shift from a worldview comprising linear systems to that of nonlinear systems. This shift in paradigm allows for a more complex understanding of how systems work but reduces the scientific certainty that cause-and-effect relationships offer. To explain chaos theory and how it relates to the area of crisis management, this article explains the major components of chaos theory that are widely applied metaphorically to crisis situations.

Sensitive Dependence on Initial Conditions

Sensitive dependence on initial conditions is commonly referred to as the “butterfly effect.” Complex systems are open and sensitive to environmental influences, and these stimuli may affect many parts of the system directly or indirectly. The butterfly effect explains that within systems are complex relationships between the parts, which may cause some parts of the system to interact and behave in unexpected or seemingly random ways. The butterfly effect explains that small variations in the initial conditions of the system can have a large and disproportional impact on a system’s future behavior. For example, the introduction of a new species to an ecosystem can radically change the entire ecosystem because of the complex relationships within the system. As applied to crisis management, the butterfly effect illustrates the need for emergency professionals to remain mindful of how crises are complex and different and to avoid treating similar crises as identical.

Fractals

Fractals are naturally occurring phenomena that are used by crisis management scholars to represent and explain complex system behavior. A natural fractal that is commonly referred to in the crisis literature is a head of Romanesco broccoli. Looking at the head of broccoli, several scales are visible simultaneously. “Scale” refers to the vantage from which we observe an object or phenomenon. The scale at which something is observed dramatically affects the perceptions or reality of what is being viewed. For example, looking at our first scale of the entire head of broccoli, we see there is an identifiable, repeating pattern in the broccoli’s overall design. As we move toward a smaller scale, the individual florets, there is a similarity in the pattern between the head and the floret. At an even smaller scale, the buds on the florets repeat the same pattern as those found at the previous two scales. Although the design of the broccoli may change slightly from scale to scale, the “self-similar” pattern is repeated. Chaos theory holds that if one observes a single event at too close a scale, it is impossible to determine an



Fractals allow multiple scales to be viewed simultaneously. An example of a naturally occurring fractal that is commonly used in crisis literature is a head of Romanesco broccoli. Several scales, or vantage points, are simultaneously visible in the whole head of broccoli, which shows a repeatable design. On a smaller scale, there is a similarity in the pattern between the head and each individual floret. At an even smaller scale, the buds on the florets repeat the same pattern as those found at the previous two scales.

underlying pattern. Fractals allow multiple scales to be viewed simultaneously, revealing the true complexity of the system and the underlying patterns that are repeated throughout the system.

The word *fractal* comes from the Latin word *fractus*, which literally means broken or fractured. This ironic definition reveals a central tenet of chaos theory: there is order in disorder. The underlying order of a system is revealed in the repeating patterns of fractals. In times of rapid systemic change, this underlying order of the system works to restore stability, or "equilibrium," within the system. The pattern of the system's behavior may change in response to changes in the system (self-organizing); however, each new pattern is similar to the previous pattern (self-referencing), so that the identity of the system is preserved in the search for restored equilibrium. The search for order revolves around "strange attractors," which in the field of crisis management may be agencies such as the police and fire departments or values such as corporate mission statements and community values.

Crisis scholars have applied fractals to a variety of crisis management issues such as safety and maintenance procedures that were unable to detect changes in the system before a crisis occurred, community emergency preparedness activities that were not robust enough to confront complex emergencies, and flood prediction methods that did not account for the natural complexity of the environment to accurately predict flood levels. These applications of fractals to emergency situations illustrate that a macroscopic view of a system is useful for understanding the true magnitude of crises.

Feedback

Systems theory recognizes two distinct forms of feedback: positive and negative. Even though the types of feedback are called negative and positive, the type of feedback does not place a value on the content of the message. Instead, the types are differentiated by how a system uses the feedback. Negative feedback is seen as regulatory, while positive feedback is seen as a signal to change. Although these theoretical components are originally from systems theory, they are widely used in the application of chaos theory to crisis management.

"Negative feedback" refers to signals that regulate a system. The dashboard of an automobile has many negative feedback instruments designed to regulate the consistent operation of the vehicle. The fuel gauge provides feedback on the amount of fuel in the tank, so that the vehicle does not run out of fuel. The same type of negative feedback loop works in the human body. When a body needs food, the stomach may growl and the individual feels hungry. This negative feedback is intended to regulate energy and maintain the system's equilibrium. Examples of negative feedback loops are commonly found in the regulatory instruments used in industry to keep operations running smoothly, the observation instruments used in environmental scanning (e.g., water levels or temperature changes) to make necessary adjustments in dam levels or power needs, and maintenance procedures used to regulate safe, efficient operating conditions.

"Positive feedback" is a signal that a change is needed within the system. Positive feedback is often missed or ignored by negative feedback loops designed to regulate specific conditions. Positive feedback is usually outside the norm of what regulators commonly look for, and over time these ignored signals are amplified throughout the system. Eventually, the system reacts in a massive and surprising reorganization in an attempt to adapt to the change in the system. This reorganization is often found to be the cause of bifurcation points (see below) that lead to many large and complex crises, because the surprising behavior of the system often overwhelms the expectations and preparations of organizations. By recognizing positive feedback through mindful observations, a system can help organizations recognize problems and stabilize the system before it escalates into a crisis situation.

An example of positive feedback can be understood through the feedback noise of a microphone. The squealing noise is the result of the same noise being amplified over and over, and something must be changed in the system for the squealing to stop. Adjusting the volume of the amplifier, moving the location of the speakers, or changing the way the voice enters the microphone is necessary for the squealing noise to subside and normal operations to resume. While the squealing noise is occurring, the entire system is disrupted and unable to function. Some examples of positive feedback in the practice of crisis management may include strange instrument readings that may be disregarded because they are unexpected, small failures that are temporarily fixed but the root causes are ignored or unknown, or strange variances in system behavior that do not cause immediate harm and are not pursued because the system temporarily recovers. Such positive feedback is often ignored for continued efficiency; however, the cost of ignoring positive feedback may be great when a crisis results.

Bifurcation

Bifurcation refers to the process when a system radically changes its behavior, identity, and/or structural makeup to respond to changes in the environment. When a system's routine is no longer able to maintain the status quo of operations, the system adapts its behavior creatively to evolve with purpose (greater resiliency). These adaptations are bifurcations, which split from the status quo. "Bifurcation" means to split into two, but a system can undergo rapid bifurcation in times of crisis to provide the system with multiple options for adaptation. Bifurcation points are often met with fear because the system can change so radically that individuals lose the ability to make sense of the situation. However, in organizations that survive bifurcation, the system evolves creatively with increased complexity to a new environment. If a system is successful in its evolution, it will be more resilient to similar events in the future. After a bifurcation, the system will not return to the status quo. Instead, the system will be changed forever and operate in a "new normal."

Crisis management scholars use the component of bifurcation to explain how the onset of a crisis or trigger event occurs, magnifies, and radically affects the entire system. Bifurcations result in increased complexity and restructuring that enable surviving organizations to be more successful in a new normal.

Chemical Risk

Transportation incidents, industrial accidents, plant fires, natural disasters, and terrorist attacks can result in the high-level release of chemicals. When a crisis arises following an accidental or intentional chemical release, the specific physical, chemical, radiological, and toxicological risks must be identified. Whether the chemical is a solid, liquid, or gas can present significantly different oral, dermal, and inhalational risks. Chemical properties such as flammability, pH, and reactivity with water or other chemicals are crucial characteristics to understand in order to mitigate the hazards they represent. Chemical properties of ionization, flammability, and reactivity can also be utilized to monitor the ambient conditions for the presence of chemical hazards. Toxicological effects can be localized or systemic, immediate or delayed, and may require specific antidotes for treatment. Crisis management of chemical risk therefore requires a thorough understanding of the various hazards presented by the specific properties of the chemical or chemicals involved. Ultimately, individuals properly trained to handle hazardous chemicals should conduct emergency response operations.

Physical Properties

The physical form of a chemical (i.e., liquid, solid, gas) and other physical properties such as smell, density, and volatility can affect the level and nature of chemical risk. Gases that are heavier than air can concentrate in low-lying areas, while those lighter than air will be more likely to disperse and minimize potentially hazardous exposure concentrations. Liquids need to be contained to prevent uncontrolled migration. Dense liquids will sink to the bottom of waterways, while less dense liquids will float and affect the shoreline. Miscible liquids like ethanol can severely alter oxygen content, affecting aquatic life. Highly volatile liquids can create inhalation hazards. While some chemicals have odor thresholds that provide good warning properties, many others are hazardous when no odor is detectable. Solids are typically less mobile than gases or liquids, but powders, granules, or dusts can create significant airborne particulate hazards during windy conditions.

Chemical Properties

Chemical risks are frequently defined by the chemical properties of flammability, corrosivity, decomposition, and pH. Corrosives are chemicals with extremely high or extremely low pH that can cause irreversible tissue destruction at the site of contact. Many irritants are diluted corrosive chemicals present at a more neutral pH. Hazardous decomposition products can be formed when a chemical compound breaks down because it is unstable, or reacts with common environmental chemicals such as water or oxygen. There are flammable gases, liquids, and solids.

Chemical properties can also be utilized to monitor airborne levels of chemicals. Lower explosive limit (LEL) detectors can be used to monitor for flammability and explosive hazards. Photoionization detectors (PID) are portable chemical monitors that can be used to measure the concentration of a wide range of volatile organic compounds. Colorimetric detector tubes take advantage of specific chemical reactions to quantify chemical concentrations.

Toxicological Properties

Toxicological properties are properties of a chemical that can manifest adverse health effects if individuals are exposed over sufficient concentrations and time frames. Toxicological risks are investigated and quantified by a variety of regulatory, industry, and advisory organizations. Risk assessments extrapolate from epidemiologic, clinical, toxicological, and environmental research and infer the risk of potential harm to people. This process results in formulation of health-protective guidelines. Toxicological effects tend to vary depending on the length of exposure. As such, exposure guidelines are published for specific time frames to account for short-term (acute) and long-term (chronic) effects. Additionally, exposure guidelines are determined for different populations such as workers and the general population, which includes sensitive subgroups such as children and the elderly.

In the United States, the Occupational Safety and Health Administration (OSHA) Permissible Exposure Limits (PELs) are legally enforceable values set to protect worker health and safety. However, the regulatory process limits timely updates of these values, and therefore, exposure levels published by member-based organizations like the American Conference of Governmental Industrial Hygienists (ACGIH) are frequently more representative of the current understanding of the hazards presented by workplace exposure to hazardous chemicals. The American Industrial Hygiene Association (AIHA) publishes Emergency Response Planning Guidelines (ERPGs) that estimate the concentrations at which most people in the general population will begin to experience health effects if they are exposed to a particular chemical for one hour. Protective Action Criteria (PAC) and Acute Exposure Guideline Levels (AEGLs) are additional guidance values aimed at protecting the general public. The European Chemical Substances Information System (ESIS) also provides a variety of chemical information. Long-term environmental cleanup levels are published by federal and state agencies for air, soil, and water. These include the risk-based screening levels (RSLs) published by the U.S. Environmental Protection Agency (EPA).

Emergency Response

All workers who are involved in operations that may involve exposures or potential exposures to hazardous chemicals should receive specific training to ensure that they are able to perform their duties without endangering themselves or others. In the United States, the OSHA Hazardous Waste Operations and Emergency Response Standard (HAZWOPER) mandates this training. The specific physical, chemical, radiological, and toxicological risks as well as the site-specific considerations are all factored into a plan to mitigate the hazards of the chemical release. Appropriate types and levels of personal protective equipment (PPE) need to be determined and available to workers involved in the remediation. Environmental testing will ultimately reveal when the site has been adequately remediated.

Chemical Weapons

Chemical weapons involve the use of chemical agents and their toxic properties against military forces or specific populations during chemical warfare. Chemical agents used as weapons have been called "the poor man's atomic bomb," primarily because chemical agents are easier to acquire than a nuclear weapon but can have devastating effects on their target population. Additionally, chemical agents can exist in gaseous, aerosol, and liquid states and can be dispersed through a variety of routes depending on their desired effects.

The following expands on the concept of chemical warfare by providing a history of chemical warfare and the use of chemical agents; the different categories of chemical agents, including their health effects and treatment; and essential elements to identify chemical agents.

The History of Chemical Warfare

Research tells us that chemical weapons have been used for over a thousand years. They have been used to conquer armies and to terrorize society throughout history.

Ancient history reveals numerous cases of the use of chemical weapons. In the fourth century B.C.E. during his campaign in India, Alexander the Great and his army were attacked with poison arrows and incendiaries that created suffocating smoke. There is also evidence that as far back as 1000 B.C.E. China used burning balls of mustard and other toxic plants to smoke out its enemies hiding in tunnels. Additionally, the Spartans attacked Athens, Greece, using a combination of wood, pitch, and sulfur to create a noxious smoke, hoping to incapacitate their enemy.

Later, during the American Civil War, a New York schoolteacher proposed the use of chlorine gas in artillery shells. However, there is no evidence that this idea was ever used.

The Germans were the first to use chemical agents in artillery shells during World War I. There is evidence that they used a form of bromide against the Russians and chlorine gas on the French, Canadian, and Algerian troops. However, it is a fact that chlorine, phosgene, and mustard gas were used by both sides, resulting in over a million casualties and tens of thousands of fatalities.

During the Iran–Iraq War in 1980, Saddam Hussein ordered the use of mustard gas and the nerve agent tabun. An estimated 100,000 Iranian solders were victims of chemical attacks. Many were casualties of mustard gas, and approximately 20,000 were killed by the nerve agent.

In the spring of 1995, the Japanese cult and terrorist group Aum Shinrikyo perpetrated an attack on the Tokyo subway with the nerve agent sarin. Even though the group's method of dispersing the sarin was not as effective as planned, it still resulted in the death of 12 persons and exposure of approximately 160 to the nerve agent; another 5,000 worried and thought they had been exposed. The medical facilities were overwhelmed, and the city was in a panic. The Aum Shinrikyo had succeeded in terrorizing Japanese society.

Categories of Chemical Warfare Agents

There are six categories of chemical warfare agents. Originally there were five, but tearing agents are often listed separately from incapacitating agents.

1. Nerve agents include sarin, tabun, soman, and VX. They have properties similar to pesticides in high concentrations. Their health effects include the following:
   - Exposure through inhalation and/or direct contact with skin
   - Loss of bodily fluids through vomiting, diarrhea, and saliva
   - Abdominal pains
   - Muscle twitching and weakness
   - Visual difficulties
   - Loss of consciousness
   - Convulsions
   - Difficulty breathing

   Treatments for nerve agents include the following:
   - Remove victim from source of exposure
   - Decontaminate clothing and skin
   - Administer antidotes: atropine, pralidoxime, and diazepam
   - Ventilation
2. Blister agents include mustards, lewisite, and phosgene oxime. Their health effects include the following:

- Exposure through inhalation and/or direct contact with skin and eyes
- Reddening of skin
- Blisters filled with liquid
- Sloughing of skin
- Damage to lungs with pulmonary edema
- Immediate severe pain with lewisite

Treatments for blister agents include the following:

- Remove victim from source of exposure
- Decontaminate immediately to prevent damage
- Irrigate eyes
- No antidote for mustards or phosgene oxime—only supportive care
- Antidote for lewisite is dimercaprol

3. Choking agents include ammonia, chlorine, hydrogen chloride, nitrogen oxides, phosgene, and phosphine. Their health effects include the following:
   - Irritate and damage throat, airways, and lungs
   - Choking and shortness of breath
   - Can also irritate eyes

Treatments for choking agents include the following:

- No antidote available
- Only supportive care

4. Blood agents include hydrogen cyanide and cyanogen chloride. Health effects of blood agents include the following:
   - Hyperventilation
   - Headache
   - Dizziness
   - Vomiting
   - Convulsions
   - Breathing may stop within 3–5 minutes
   - Cardiac arrest
   - Cyanogen chloride may also irritate eyes, airways, and lungs

Treatments for blood agents include the following:

- Ventilate
- Administer antidotes: sodium nitrate and sodium thiosulfate

5. Incapacitating agents are chemical agents used to incapacitate rather than kill their intended victim(s). These types of agents include hallucinogens such as LSD and vomiting agents like Adamsite. Their health effects include the following:
   - Hallucinogenic agent effects can last for an hour to days
   - Confusion
   - Sleepiness
   - Hallucinations
   - Loss of concentration
   - Delirium
   - Vomiting
   - Headache
   - Nausea
   - Diarrhea
   - Abdominal cramps
   - Changes in mental status
   - Death can occur with excessive exposure

Treatments for incapacitating agents include the following:

- Supportive care
- Symptoms may dissipate over a few hours to days

6. Tearing agents include tear gas and pepper spray, which are used for riot control or to defend against individual attackers. Their health effects include the following:
   - Severe burning sensation and tearing of eyes
   - Irritation of nose and throat
   - Coughing
   - Difficulty breathing
   - Vomiting
   - May cause scarring and permanent damage

Treatments for tearing agents include the following:

- Remove victim from source of exposure
- Irrigate eyes

Identifying Chemical Agents

There are six essential elements that assist in identifying the chemical agent.

1. Characteristics
   - Descriptive elements:
     - Color (i.e., VX is amber in color)
     - Odor (i.e., mustard smells)

    - » Consistency (i.e., VX is oily)
    - » Physical state:
    - » Vapor (i.e., sarin can be dispersed as a vapor)
    - » Aerosol (i.e., Adamsite is disseminated as an aerosol)
    - » Liquid (i.e., VX is a liquid hazard)
    - » Persistency (i.e., VX can remain on the ground for weeks, while sarin evaporates quickly)

2. Toxicology
    - » Average incapacitating dosage
    - » Average lethal dosage
3. Physical findings (see above)
    - » Symptoms of the victims
    - » Large number of dead animals in an area
4. Protection required
    - » Personal Protective Equipment (PPE) may be mask only or protective suit
    - » Immediate action(s) may include moving out of the contamination
5. Medical management (see above)
    - » Antidotes
    - » Treatments
6. Decontamination
    - » Neutralize using copious amounts of soap and water
    - » Chemical destruction by using a solution of bleach for contaminated surfaces

Conclusion

This overview on chemical warfare, including some of the history of chemical warfare and the use of chemical agents; the different categories of chemical agents, including health effects and treatment; and the essential elements to identify chemical agents provides only a baseline for understanding chemical warfare. Further study and research is required to identify the essential elements for each chemical agent and to know how to effectively respond in the event of a chemical attack.

Chief Security Officer

Organizations must go beyond managing risks in silos and build an enterprise-wide risk management (ERM) function so that a full spectrum of risks is addressed wisely, systemically, and professionally. As a business enabler, corporate security should be integrated into the overall risk management framework, resulting in deeper penetration into business risks. The demand has grown for a more holistic approach to corporate security management. For example, the convergence of information technology (IT) security needs to be more closely aligned with physical security and other corporate security functions under the umbrella of ERM. Such a convergence is especially necessary for the protection of an organization's brand and reputation as a result of improved risk intelligence sharing, collaborative decision making, and strategic risk focus and oversight from the top.

Former Deloitte Chief Executive Officer (CEO) Bill Parrett also provides new insights into corporate security and risk management. In his book *The Sentinel CEO: Perspectives on Security, Risk, and Leadership in a Post-9/11 World* (2007), Parrett gives his views that following 9/11, the security of physical assets and other major security events such as pandemics and terrorism, as well as technology hackers, are top of mind for business executives today. ERM has become an increasingly visible and important management solution, especially for the newer and more complex risks. Parrett also recognizes the ascension of the chief security officer (CSO) as a new senior-level position on the corporate organizational chart that is fast becoming a key decision maker in the top management of many U.S. companies and an indispensable ally of the CEO.

The "FIBER" Corporate Security Model

One corporate security approach is found at Deloitte, where FIBER is a practical model for the protection of all organizational assets with physical, personnel, and information security mechanisms as well as crisis management and business continuity strategies. This model provides combined security and safeguards as needed to protect the five asset classes: facility, information, business, employee, and reputation (FIBER).

According to this model, security is a value-added service with an emphasis on proactive prevention rather than reactive enforcement. All security programs are based upon threat and risk assessments and security recommendations tailored to individual and facility requirements. Security is everybody's business. The vigilance and involvement of every employee is needed under the leadership and guidance of a professional and competent security organization. The key protection principles of "deter, detect, delay, and respond" are used to provide a total security risk mitigation response.

The FIBER corporate security model demonstrates that for risk assessment purposes, the consequence analysis should estimate the potential impacts on all five primary asset classes. Recent high-profile international crises and blunders continue to show that reputational risk can pose the greatest threat to an organization's stability and value and result in drastic implications for the companies involved. It is important for reputational risk to be fully integrated into risk assessments. During a crisis, business leaders may also overconcentrate on the impacts on facility and business at the expense of people risk. For example, the lack of a robust crisis management plan and team could lead to a full-blown situation that is discernible to the public and ultimately become a trust issue both internally and externally.

Enterprise Security Risk Management

Enterprise security risk management (ESRM) exists to ensure that the risks traditionally associated with security but not always covered by ERM are properly considered and treated. In order for ESRM to be successful, corporate security needs to be able to collaborate seamlessly with other control functions, such as compliance and internal audit, to enhance the organization's security posture. In the course of implementation, corporate security would also need to build effective interfaces with other key support functions, such as human resources, communications, legal, IT, safety, and facilities management. Not only does the CSO need to understand the security threats and risks to the organization and its people, but he or she should also take an active role in understanding the nature of business operations, environments, and events in order to be able to analyze any potential reputational risk implications. An organization should focus on the following key areas to maximize the value of security and pursue security risk mitigation proactively:

- Physical security
- Information security
- Personnel security
- Crisis management
- Business continuity

In addition, there should be a systematic approach to acquiring and analyzing the risk intelligence necessary to support senior leaders of the organization in the protection of assets and the allocation of security resources. A corporate security risk assessment methodology consistent with that used by risk management should be adopted to analyze threats and vulnerabilities, assess risks to the organization, and develop recommendations for enterprise-wide risk mitigation. Senior management also needs to engage with the security agenda to set its risk appetite in navigating the risk landscape.

Corporate Security Programs

In greater detail, the following corporate security programs should form the baseline security initiatives that a CSO should focus on the following:

- Security strategy planning
- Security planning for significant events
- Security review/capability assessment/gap analysis
- Security risk assessment
- Physical security threat and vulnerability assessment
- Emergency response planning
- Crisis management planning
- Travel security program
- Private executive protection program
- Pandemic planning
- Business continuity planning
- Security education and awareness workshop/training
- Privacy and information protection
- Corporate investigation
- Drills and exercises

A Risk-Intelligent Chief Security Officer

A risk-intelligent CSO should understand the dynamics between corporate security and enterprise risk management. All primary asset classes should be duly considered for a total asset protection under ERM. According to the FIBER security concept, the consequence analysis should cover any impacts on facility, information, business, employees, and reputation. A simple, consistent, and effective security risk assessment methodology, an early security warning system, and the supporting major corporate security initiatives that a CSO should focus on in his/her everyday professional life are important elements for enterprise security risk management to be successful.

Cholera

Following every natural disaster, one of the most common and rapidly spreading outbreaks, affecting hundreds of people around the developing countries of Africa, Asia, and Latin America, is cholera, contracted after a person is infected by the *Vibrio cholerae* bacterium. Patients suffer from frequent diarrhea, which often escalates into dehydration and even death. Treatment options for the disease generally include oral rehydration and a course of antibiotics to reduce the effects of the disease. However, during any post-disastrous event, providing victims access to both can be challenging and requires proper management; coordination is needed before, during, and after an outbreak occurs.

Pre-Outbreak Management

In preparing for any disastrous situation, the key step that needs to be taken is to identify the people who will likely be affected by the disaster, the services and resources that are likely to be needed, and, finally, the responsible party who is willing and has the capacity to provide the required services. Before a cholera outbreak occurs in vulnerable areas, it is therefore necessary to first identify highly populated areas with possibly contaminated drinking water and poor sanitary conditions. Once these areas are identified, the next step is to form a monitoring team that can confirm possible outbreaks. Members of this team should include doctors, epidemiologists, microbiologists, and water contamination and sanitation experts. Using modern database and mapping software, including geographic information systems (GIS) and remote sensing, the team should try to identify the locations of the possible victims, locations of the contaminated water sources, and locations of sanitation facilities, as well as the nearest possible clinics and hospitals that are able to take care of patients in case an outbreak occurs. GIS can also be used to identify locations that would be suitable for setting up new treatment facilities. Although hospitals and clinics are ideal locations for treating cholera victims, sometimes larger facilities capable of handling large numbers of people (e.g., schools, churches, and mosques, etc.) would be more appropriate. These facilities should keep large quantities of safe running drinking water, good sanitation facilities, medicines, IV and rehydration fluids and energy drinks, and trained medical professionals (a full list of required resources can be found in the World Health Organization's (WHO) required cholera supply list). In situations where clean water supplies are not available, various types of on-site purification chemicals (such as chlorine) would need to be gathered and prepared for any possible outbreaks. Oftentimes, international and governmental organizations, along with local nongovernmental organizations (NGOs), are responsible for taking care of such mitigation and preventive measures.

Outbreak Management

Usually, a cholera outbreak is confirmed by epidemiologists and medical professionals once 10–20 cases are reported. Once confirmed, the first step

A Centers for Disease Control and Prevention Public Health Prevention Service cholera treatment center in Haiti, November 2010. Cholera is easily controlled in most settings, but because of the poor water quality and sanitation problems in the aftermath of the January 2010 earthquake, cholera had an ideal setting in which to spread. As a result, tens of thousands of Haitians contracted cholera.

is to notify the nearest health officials as well as the WHO. Emergency management teams need to be formed, and these teams need to collect data on the victims in terms of their locations, attack rate, areal extent of the patients, age, gender, and any other medical conditions they may be reporting. It is also essential that the general public be made aware of the outbreak. Various media outlets, including television and radio, newspapers, flyers, billboards, and loudspeakers, can all be used to notify the public. The public also needs to be notified of the symptoms and the actions they can take to save the lives of victims. The message needs to be clear, concise, and simple to understand so that poor and uneducated people (as this is often the case in developing countries) can understand and follow the instructions. As mentioned above, during the time of the outbreak, careful attention needs to be given to the purity of drinking water supplies. Separate male and female public toilets and latrines also need to be provided if they are not available, and they need to be cleaned on a regular basis. The users should also have access to antibacterial soaps and sanitizers so that the public can clean their hands after defecation. When preparing foods, kitchen areas should be clean, and raw fruits and vegetables should be separated from cooked foods to prevent contamination. The cholera bacterium grows very well in moist environments at room temperature; therefore, foods such as milk, potatoes, beans, and eggs should never be prepared more than an hour before eating. For babies, breastfeeding is the most hygienic choice for food during the outbreak. Victims who die during the outbreak should have proper funerals with preventive measures taken in order to avoid contaminating other people with the bacterium.

Post-Outbreak Management

After any natural disaster and epidemic outbreaks, it is important to reflect on the past events in order to prepare future mitigation and emergency management plans. In cholera-endemic areas, it is essential to monitor rivers, ponds, fish farms, and other virus-causing agents so that an outbreak can be contained. Also, crisis management personnel should study previous outbreaks in order to assess what worked and what did not in terms of saving human lives. Past victims should be monitored for their health conditions and any deaths. Post-outbreak studies should also be conducted in order to identify areas, age groups, and socioeconomic conditions of the affected victims. The agencies that were involved in monitoring, testing the water contaminants, and taking care of the victims, as well as the funding agencies that provided the funds and the appropriate use of such funds, should all be examined. Looking at all of these critical issues will then facilitate effective management of future cholera outbreaks.

Civil Protection

In the field of emergency response, basic terminology is used somewhat loosely and often in ways that translate poorly between one language and another. Although the following two basic definitions may not be adhered to in the naming of particular services, they are used for the sake of developing logical arguments. Civil defense signifies an emergency response system that is centralized at the level of national government and is designed to protect vital national institutions and their functionaries, and eventually the general public, against acts of armed aggression by foreign powers or particular groups. Civil protection is a locally based emergency response system designed to protect the general public and key institutions against the effects of emergencies, crises, and disasters of all kinds and to help ensure safety at large events such as mass gatherings. Other terms used include *civil security*, *public safety*, and *emergency preparedness*. Hence, civil defense is usually a centralized, "top-down" system managed by a national government, while civil protection is a "bottom-up" system that has its roots in local organization, although it will need harmonization, support, and coordination at the national level. The primacy of national laws, and the distinctive legal and administrative systems used in different countries, means that these systems are rarely pan-national, although interoperability across national borders is becoming increasingly desirable.

Evolution of Emergency Response Systems

To understand the distinction between civil defense and civil protection, it is necessary to look back some decades into history. The antecedents of modern civil defense can be found at various points in history, including, for example, during the American Civil War. However, in its modern form, civil defense probably began on a particular morning in April 1937. This is when a flight of new Axis Messerschmitt aircraft took off from Germany to bomb the Basque town of Guernica, where there was a meeting of the Spanish Republican government. It was the first concerted aerial bombardment in history, and Pablo Picasso depicted the agony and destruction in his famous painting of the event. The quasi-spontaneous organization of protection for the noncombatant population was the beginning of a process that grew enormously during the bombardments of 1940 through 1945. Indeed, Germany ended World War II with one of the best-organized and most extensive civil defense forces of all countries.

The purpose of civil defense forces in the 1940s was to conduct search-and-rescue operations, cordon off damaged areas, put out incendiary bombs, look after the survivors, and maintain public order in areas subject to bombardments. These processes were known in Great Britain as Air Raid Precautions (ARP). The equipment used was rudimentary: often only a helmet, a canvas bag containing a gas mask, and a few torches and ropes. The personnel mainly consisted of men who, for one reason or another, were deemed unfit to send to the front as soldiers.

On March 5, 1946, during a speech at Westminster College, Fulton, Missouri, Winston Churchill noted that "From Stettin in the Baltic to Trieste in the Adriatic an iron curtain has descended across the Continent [of Europe]." The 1940s thus ended with the rise of the Cold War and a radically new role for civil defense. Preparations were made to survive a thermonuclear exchange (if such were ever possible). The emphasis was placed on underground refuges and command centers; robust, secure, and encrypted communications systems; a general air of secrecy; military forms of command and the use of paramilitary auxiliaries; and extraordinary powers ready to be assumed by governments—or their remnants. The entire system assumed that nuclear war would be survivable, but that there would be an instantaneous breakdown in public order.

The 1970s and 1980s

In the 1970s and 1980s, civil defense underwent a gradual decline. First, there was a slow withdrawal from the mentality of the Cold War, coupled with a growing sense of détente between the superpowers. Second, people and planners began to recognize the demonstrable futility of many of the preparations made to survive a putative nuclear strike, and the waste of resources that these entailed. Third, the growing effect of natural disasters demanded new and more effective forms of organization. However, in many countries progress in this last field was slow as a result of political polarization (a remnant effect of the Cold War) and the effects of corruption and, when it was unmasked, very public scandals. Nevertheless, the fall of the Berlin Wall in 1989 ushered in a new period of the decline of the authoritarianism that had motivated the civil defense of the Cold War. For a period of about five years there was also a "peace dividend," and resources could be devoted to new means of protecting the public.

As a movement, civil protection began to emerge in the 1970s in response to the cumulative effect of natural disasters in causing misery, casualties, destruction, and disruption of daily life. The end of the Cold War, and the temporary cessation of associated “proxy wars” supported in third world countries (e.g., Afghanistan) by the great powers, led to a reduced risk of coups d’êtat at home and hence fewer excuses to repress the domestic population. Meanwhile, the age of the international disaster began, with increased participation in major catastrophes (eventually, after the 2010 Haiti earthquake, 129 countries sent aid).

One catalyst was the United Nations’ International Decade for Natural Disaster Reduction (IDNDR, July 1990–June 2000). This was first proposed in 1984 as a decade for monitoring extreme natural phenomena, but once it reached the UN’s General Assembly, the representatives of low- and middle-income countries had it transformed from a technology-based scientific initiative into one that offered a chance of improving the relationship between development and disasters. In the end, 140 countries set up national committees for the IDNDR and some large transnational projects were inaugurated, as were several large conferences designed to review and promote strategy. The effects were mixed, as the Decade did not greatly reduce the effects of disaster, but it did promote international collaboration and strategic aims for disaster risk reduction. The Decade was followed by the consolidation of international mechanisms into the UN’s permanent International Strategy for Disaster Reduction (UNISDR), which continues to do much good work in this field. UN-level international disaster response, as opposed to disaster reduction, remains the preserve of the Office for the Coordination of Humanitarian Affairs (UN-OCHA).

Civil protection (often in all but name) has benefited from several trends: increased global collaboration and the sharing of knowledge, the increasing impact of information and communications technology, and improved agendas for training. Under civil defense, the typical protagonist was a middle-aged, ex-military man of a certain rank, now enjoying a second or third career in civilian life. Finally, trained young people began to appear, including those from particular ethnic backgrounds. In many cases, women proved to be particularly good emergency managers, but unfortunately they remain in the minority. There remained a pressing need to improve the local organization of civil protection services, and in diverse countries also the quality of national coordination structures.

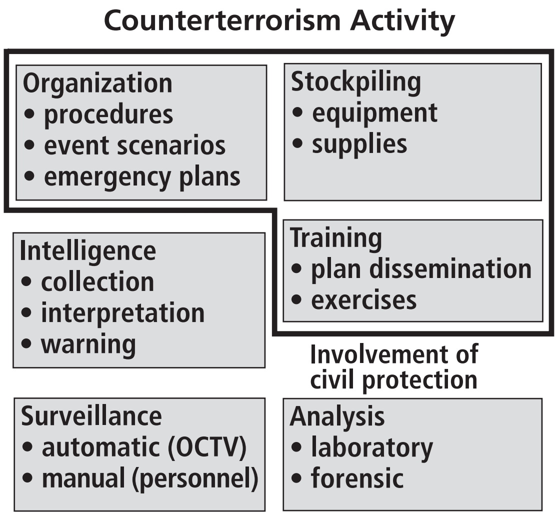

Figure 1 Involvement of civil protection forces in typical civil defense activities

Twenty-First Century

In synthesis, in the 2000s, civil protection finally distinguished itself from civil defense. It is organized at the local level (predominantly that of the municipality), with support and harmonization from higher levels of government. It is explicitly a service for the general public, and it tackles natural and anthropogenic risks of a nonbellicose nature. Figure 1 indicates how civil protection participates in only some of the actions attributable to civil defense. Hence, there is a connection, but it should not lead to the subsuming of civil protection into the civil defense system.

The events of September 11, 2001, in the United States rapidly consolidated a trend that had begun to emerge a handful of years before. This was the return of civil defense in a new form. The name chosen for it in the United States was Homeland Security. The threat of armed aggression from particular nation-states had lessened (other than in covert form by proxy), and it had increased from dissident groups. This required reorganization on the part of national forces to combat the emerging and mutating threats of domestic and international terrorism. In the United States, the Federal Emergency Management Agency (FEMA), responsible in all but name for civil protection, was subsumed under the mantle of Homeland Security, which encompassed 150 national organizations and required the greatest reorganization of the federal government since the creation of the Department of Defense in 1947. For better or worse, other countries followed the lead of the United States. Many failed to note that forms of organization that are appropriate for a federal state are not necessarily ideal in a nonfederal one, in which the relationship between the central government and the regions is different from that pertaining under federation. This problem was graphically illustrated by the debacle of Hurricane Katrina, in which federal aid to the affected states was slow and inefficient, but the states themselves lacked sufficient resources and organization to respond adequately to the disaster.

Current Organization

The two words *safety* and *security* are clearly differentiated in English, but not necessarily when translated into other languages. In the simplest terms, civil protection deals with the former and civil defense with the latter. Some countries, notably Italy, have clearly articulated and fully institutionalized distinctions between the two systems, but many do not. New Zealand, for example, has a Ministry of Civil Defense and Emergency Management, whose main competencies lie in providing civil protection support to regions, districts, and municipalities affected by natural disaster, a typical civil protection role. Likewise, the *Defensa Civil* of Colombia enjoys a typical civil protection structure, with decentralized committees at local and regional levels. Some other countries have left their disaster response with a paramilitary structure redolent of earlier forms of civil defense. China effectively began to modernize its emergency response in the wake of the May 2008 Wenchuan earthquake in Sichuan Province. It remains dependent on the People's Liberation Army because of the need for copious organized human resources.

Despite the internationalization of disaster response, civil protection remains a national competency virtually everywhere. In the European Union (EU), for example, there is a Directorate General of the European Commission (the executive body of the EU) that deals with disaster response at the supranational level, largely through the EU's Monitoring and Information Centre (MIC). A report written in 2005 by Michel Barnier, the former French foreign minister, recommended the setting up of a transnational European disaster response force, but it has not been implemented. The EU's 27 nations and various affiliates have five different legal systems and all the differences in public administration that stem from contrasts between monarchies, federal republics, island states, centralized republics, and so on. A single European civil protection organization is thus virtually impossible, although advances in interoperability are both possible and sorely needed.

Two models of organization pioneered by Italy have gained traction in other European countries and elsewhere. Commonly, at the national level, civil protection is an organ of the ministry of the interior (or similar agency), with the minister as nominal head of the service. In 2000, Italy briefly experimented with making the national civil protection organization an independent agency but found that the level of financial dependency on other organs of government was too great for this to be effective. Hence, it made the Italian Department of Civil Protection a dependency of the national cabinet under the nominal headship of the prime minister. The advantage lies in increased efficiency of relationships with other ministries, notably health, public works, and economic affairs. This arrangement was made a nonbinding directive of the European Union and was adopted by, among others, the United Kingdom and Sweden.

The second model involved a fusion between domestic and overseas disaster response (and in the case of Italy also cross-boundary European response). As the same forces and command structures have often been used in both (or all three) kinds of operations, it made sense to amalgamate their administrative structures. Subsequent to this, the European Commission created a new Directorate General that fused the civil protection arm, formerly under DG Environment, and the European Communities Humanitarian Office (ECHO).

The essence of good emergency response and management is that there be a complete system, with a strong base at the local level, especially that of the municipality. There also needs to be a cascade of information, resources, and command such that the national and international levels of disaster response are properly connected to the regional and local ones. In virtually all countries, the system is a mosaic of different levels of development, in which there are points of innovation and areas of laggard underdevelopment. The worst cases are those in which international forces and United Nations Disaster Assistance Response Teams (DARTs) must take over because of a lack of local and national forces. The international disaster response system is by nature inefficient, as resources (e.g., search-and-rescue forces) that should be present locally need to be flown long distances, with attendant delays and possible logistical shortcomings upon arrival. Other countries, such as Colombia, have systems that are excellent on paper but largely absent when one arrives in the regions and searches for the relevant agencies and organizations.

Civil protection is a cooperative enterprise that requires the conjunction of government forces, the private sector, and civil society organizations. In the United Kingdom, key private companies are required by law to prepare for disaster and participate in the emergency response system. These include the providers of public utilities and transportation. The role of civil society organizations is highly variable from one country to another. Most of these are voluntary organizations. Whereas the age of spontaneous voluntarism in disasters is well and truly over, the degree to which volunteer societies are organized, given a role in disaster response, and endowed by law with rights and responsibilities varies markedly. In Germany and Italy, volunteer organizations are the backbone of the system. Technisches Hilfswerk (THW) has 630 bases in Germany; the Venerable Company of the Misericordie has been providing volunteer disaster assistance in Italy since 1244 C.E. Voluntarism is a key element of the civil protection system in Australia, where many communities are too small and isolated to be served adequately by salaried forces. Elsewhere, it is much less significant. In Abu Dhabi, for example, organized voluntarism is a newly established element of the civil protection system.

New Trends in Civil Protection

The civil defense forces of the 1940s were paramilitary and governed by military command procedures. Ever since then, there has been a gradual process of demilitarization of civil protection. The extent to which it has occurred is virtually a measure of the degree of evolution of an emergency response service. One reason is that it is now widely recognized that authoritarian approaches to the management of civilian emergencies are counterproductive. Second, the impact of information and communications technology, now widely used in emergency management, has been to flatten the chain of command. There is now more emphasis on autonomous task forces than on command and control. More weight is given to collaboration and information sharing than to obeying orders. Third, training and improvements in equipment have greatly increased the professionalism of civil protection operatives, whether they are first responders or emergency managers. Finally, emergency planning has begun to emerge as a distinct profession and to differentiate itself from military planning (it bears a stronger resemblance to urban and regional planning than to battlefield tactics).

At the same time, new challenges have emerged that will doubtless endow the process of adaptation with yet more stimuli. Natural and anthropogenic hazards are constantly changing, and so is the balance between vulnerability and resilience in society. Civil protection forces must participate in the emerging endeavors of disaster risk reduction, the creation of resilience, and the promotion of safe, sustainable lifestyles. Climate change may increase the imperative to bring the disasters problem under control. Emerging risks—for example, those associated with pandemic influenza—threaten to change the civil protection landscape abruptly and radically, and they require substantial adaptation of plans and organization. Meanwhile, the general public's demand for safety and security fluctuates with the varying salience of disasters on the public agenda.

In the near future, the relationship between civil protection and civil defense (however they are referred to and dealt with in each country) will continue to be an uneasy one. Civil defense has responded to asymmetric threats with a series of measures designed to provide security to the public that have instead put civil liberties seriously under threat. Yet the biggest challenge of the present century is to democratize the response to the threat of disaster. The risks are simply too large to be borne solely by professional planners and responders: The general public must necessarily assume part of those risks itself. This requires not reduced liberty but participatory governance. The public must be induced to take disaster risk seriously and ensure that civil protection is a well-supported service that is applicable to all constituencies in society and is sustainable through economic downturns and all other socioeconomic changes.

Civil War

A civil war is a war between organized groups within the same nation-state. It is a high-intensity conflict, often involving the armed forces of the state against irregular armed forces, that is organized, large scale, and sustained over a fairly lengthy period of time, for example, Lebanon in 1975–90. The aim of one side may be to take control of the country, for example, Liberia from 1989 to 1996 and again from 1999 to 2003, or to achieve independence for a region, for example, Biafra from Nigeria from 1967 to 1970, or to change a government, for example, Libya in 2011, or its policies. It generally results in a large number of casualties and uses significant resources. On average, civil wars, since the end of World War II, have lasted for at least four years.

According to the 1949 Geneva Conventions, four conditions define an armed conflict amounting to a civil war. First, at least one side must have control over a part of national territory; second, the insurgents must exercise some authority over the population within a section of that national territory; third, the insurgents must be recognized as having a fighting capability; and fourth, the recognized government uses its regular military forces against the insurgents, who must themselves be organized as a military force.

Causes of Civil War

Between 1945 and 1999, there were 25 wars between different countries in which at least 100 people were killed on each side and the overall total exceeded 1,000. The total number killed in battle during these 25 wars is estimated to be 3.33 million. In contrast, in the same period, there were approximately 122 civil wars in which at least 1,000 people were killed, and the total number killed, at a conservative estimate, is 16.2 million. Excluding anticolonial wars, which amounted

Case Study: Civil War in Angola

It was not until the early 1940s that the country of Angola—a Portuguese colony for 400 years—was constituted as it is known today. Although independence was not achieved until November 1975, two groups—the People's Movement for the Liberation of Angola (MPLA) and the National Front for the Liberation of Angola (NFLA), operating from neighboring countries—commenced a guerrilla campaign, known as the Angolan War of Independence, as far back as 1961. Five years later, a third group, the National Union for the Total Independence of Angola (UNITA), was formed. The civil war can be broken into three periods separated by two periods of relative peace. The first period, from 1975 to 1991, was followed by less than a year of relative calm before hostilities occurred again from 1992 to 1994. This was followed by three years of peace until 1998. There was then renewed conflict until, in 2002, the MPLA finally prevailed.

The Early Years

The Alvor Accord, signed by Portugal and the three independence movements—the MPLA, UNITA, and FNLA—in 1974, called for a transitional government comprising all three. However, when the Portuguese left in 1975, the leader of the MPLA, Agostinho Neto, backed by the Soviet Union and Cuba, declared the formation of the People's Republic of Angola. UNITA, led by Jonas Savimbi, and supported by the United States and South Africa, declared the country would be known as the Social Democratic Republic of Angola with its headquarters in Huambo, and the FNLA declared that the country would be known as the Democratic Republic of Angola, based in Ambriz. Twelve days later, the FNLA and UNITA became allies, proclaiming a coalition government in Huambo with co-presidents and co–prime ministers.

Neto died in 1979 and was succeeded by Jose Santos, and throughout the next nine years there were continuous hostilities between the MPLA, claiming to be the legitimate government, and UNITA. In 1988, South Africa, Cuba, and Angola agreed to cease-fires in Angola and neighboring Namibia as part of a regional peace deal. Namibia, which was a colony of South Africa at the time, had been used as a military and strategic support base for operations against the MPLA. Later, a largely U.S.-brokered treaty signed in New York by the protagonists paved the way for independence for Namibia and the withdrawal of Cuban troops, which by then numbered 50,000, from Angola. The United Nations agreed to a verification mission (UNAVEM I; Security Council Resolution 435 [1988]}, which oversaw the complete withdrawal of Cuban troops. However, despite a cease-fire agreement, the fighting continued. With the Cold War still ongoing, whatever its internal causes, Moscow and Washington saw the Angolan civil war as a subplot in the global balance of power. As a result, UNITA leader Savimbi made a number of trips to the United States, where he met with both Presidents Ronald Reagan and George H. W. Bush.

In May 1991, Savimbi and President Santos met in Lisbon, with the Portuguese government acting as mediators. The result was the Bicesse Accords, which laid out transition to a multiparty democracy under the supervision of the Security Council's UNAVEM II Mission (Resolution 696 [1991]), which lasted until February 1995. Elections for president were held in which Santos received 49.57 percent of the vote and Savimbi 40.6 percent. Savimbi, together with a number of other election observers, claimed that there had been irregularities but, in any event, because no one had received 50 percent, another round was necessary. Negotiations on how and when another election should be conducted quickly broke down, and there was renewed fighting.

The following year, 1993, a major battle between government forces and UNITA, which lasted from January to March and which cost 12,000 lives, ended with UNITA victorious. Although by this time the United States and South Africa had stopped aid to UNITA, military supplies continued to come from Zaire. By August, UNITA controlled 70 percent of territory, but government forces rallied and, in just over a year, were back in control of 60 percent of the country, forcing UNITA to sue for peace. The result was the Lusaka Protocol of October 1994, under which there was to be a government of reconciliation, joint armed forces (FAA), and a national police force (ANP). In February 1995, UNAVEM III (Security Council Resolution 979 [1995]) took over from UNAVEM II to assist in the restoration of peace and to oversee the achievement of national reconciliation.

In March 1996, Santos and Savimbi agreed to form a coalition government, and in June, Savimbi was offered the post of vice president under Santos. Savimbi accepted the position in August and announced the end of the civil war in Angola. However, he had second thoughts and refused it, as a result of which Parliament abolished the position. Nevertheless, in April 1997, the Government of Unity and National Reconciliation (GURN) was formed, but further progress was seriously undermined by UNITA's failure to comply with the terms of the Lusaka Protocol. As a consequence, in August 1997, the UN Security Council imposed sanctions on UNITA (Resolution 1135 (1997), prohibiting UNITA leaders from traveling abroad, closing UNITA embassies abroad, and making the area controlled by UNITA a no-fly zone. In June 1998, UNITA's bank accounts abroad were frozen (Security Council Resolution 1173 (1998).

To assist with the peace and reconciliation process, the Security Council authorized the setting up of a peacekeeping force, MONUA, on June 30, 1997 (Resolution 1118 [1997]), to oversee the extension of government control over the whole country, and the demilitarization of UNITA forces, and to ensure the neutrality of the Angolan National Police. Meanwhile, the United Nations, with the support of three observer states—Portugal, the Soviet Union, and the United States—continued its efforts to bring Santos and Savimbi together to overcome their deep-rooted mistrust of each other.

A lack of significant progress, for which, again, UNITA was held responsible, meant that the United Nations extended MONUA's mandate every three months until February 26, 1999. In June 1998, the secretary-general reported to the Security Council that there had been a marked deterioration in the security situation in the country, which included new mine-laying activities, the deaths of civilians and the destruction of property, and displaced persons fleeing into neighboring countries. Further deteriorations, including the loss of UN aircraft over UNITA-held territory, meant the Security Council finally terminated MONUA's mandate, and most of its forces left by the end of March 1999, although the UN maintained a presence there through the establishment of the United Nations Office in Angola (Resolution 1268 [1999]).

Dissatisfied with Savimbi's leadership, a number of UNITA commanders formed a breakaway group, UNITA Renovada, in late 1998, after which Santos refused to negotiate with Savimbi, only talking to the breakaway group. Over the next two years, many more deserted Savimbi, and in February 2002, he was killed by government forces. The leadership of UNITA was briefly taken over by the vice president, but he died of natural causes less than a month later, so the leadership passed to Secretary-General Paulo Lukamba. The following month, the government announced the cessation of military operations, and commanders from both sides met to agree on the terms of a cease-fire; a Memorandum of Understanding was signed as an addendum to the Lusaka Protocol. UNITA's new leadership demobilized its armed forces in August and declared itself a political party.

Illegal Arms

During the latter stages of the conflict, a ban on weapons was violated on numerous occasions, with the Angolan government acquiring arms and equipment from, among others, the Ukraine, the Czech Republic, India, Kazakhstan, and Slovakia, while UNITA acquired its arms and equipment from countries such as North Korea. False documents were used to describe the contents of the freighters delivering the arms.

Funding the War

UNITA's funding for the war, particularly when support from the West declined, came primarily from the mining of diamonds. Despite international sanctions, it is estimated that UNITA received nearly $4 billion from diamond sales, much of which was spent on the acquisition of arms. Hence came the term sometimes used with regard to Angola and other diamond-producing African states involved in civil wars: blood diamonds.

Effects of the Angolan Civil War

Between 1975 and 2002, an estimated 500,000 people were killed during the war and well over 4 million people—approximately one-third of the population—were displaced. The war devastated the infrastructure and administrative setup left behind by the Portuguese and effectively prevented any economic growth. At the end of the war, the United Nations claimed that up to 80 percent of Angolans lacked basic medical care, 60 percent lacked access to clean water supplies, and 30 percent of children were dying before reaching the age of 5 years; life expectancy was less than 40 years. A product of this particular war, as has been the case in other parts of Africa, was the use of child soldiers by all sides and the forceful marriage of underage girls to soldiers, particularly to those belonging to UNITA. It is estimated that during the war, approximately 15 million land mines were laid. A demining operation that commenced as far back as 1994 is not expected to be completed until 2014.

to 13, the regions most prone to civil war during this period were Asia and sub-Saharan Africa (over 30 each); north Africa and the Middle East, followed by Central and South America (17 and 14, respectively); Eastern Europe and the former Soviet Union (9); and finally, Western Europe (2).

Some of the early civil wars following the end of World War II were, in fact, anticolonial wars; some people suggest these were wars of liberation but, given the above definition, they consisted of the armed forces of the state against irregular armed forces, such as the French military forces against the National Liberation Front (FLN) in Algeria (1954–62). On a number of occasions, these civil wars have also been described as insurgencies or guerrilla campaigns. In such cases, at least during the early stages, those opposing the government forces were often quite weak, being, as they were, lightly armed and either hiding within a sympathetic population or making use of terrain (mountains or forests) that was difficult for the conventional government military forces to penetrate, or they used cross-border sanctuaries. An important aspect in terms of whether an insurgency or a guerrilla campaign is likely to grow into a full-scale civil war, in which both sides become roughly equal, is the efficiency of the government's police and military forces at the beginning of the campaign. Insurgents are more likely to survive and grow if the government forces are brutal, corrupt, poorly equipped, and not particularly efficient.

There are two main schools of thought as to the causes of modern-day civil war, led by Paul Collier and Anke Hoeffler on one side and by James Fearon and David Laitin on the other. The Collier-Hoeffler model suggests that civil war is more likely where one ethnic group in the country is dominant, as was the case in the Rwandan civil war (1990–93).

However, the Fearon-Laitin model suggests that it is not the ethnic makeup of the country that is important in the lead-up to civil war; rather, it is a country's prosperity or lack of it. Those countries that enjoy a reasonable standard of living appear almost impervious to civil war no matter what the ethnic mix is. Rather, it is the poor countries where civil war is most likely. Even there, they only occur where the government is brutal, overtly corrupt, or so weak that it does not have control over the whole country, such as in Sudan from 1955 to 1972 and 1983 to 2005.

Effects of Civil War

The effects of a civil war can be catastrophic for the civilian population. Whole communities can be displaced, making millions of people homeless. Women and children invariably bear the brunt; the number of widows and orphans can increase dramatically. Civil wars also interfere with both the physical and mental development of children by destroying schools and immersing children in a culture of violence. Worse still, some children are either forcibly recruited into or willingly join the armies of one side or the other because they see no alternative. People are prevented from meeting their basic needs because crops are destroyed or large sections of land become unusable. Although it may sometimes be the by-product of war, it is often an intentional act by one side to reduce or destroy the other side's support base. Such tactics include the planting of land mines on farmland; the deliberate destruction of crops and livestock, poisoning wells; terrorizing civilians through executions, torture, rape, conscription, and resettlement; and denying food as a weapon to displaced and starving populations.

Humanitarian Aid

Humanitarian aid or relief aid is an attempt by the international community to reduce the suffering during civil wars. It normally involves the provision of tents, food, and sanitation, thus reducing the effects of the weather, hunger, thirst, and disease. Frequently, those in greatest need are in a conflict zone during a civil war. Therefore, although an effective and well-timed humanitarian relief operation has the capacity to save thousands of lives, it is an extremely hazardous operation for the aid agencies because there have been occasions when the combatants on one side or the other have deliberately targeted aid workers to gain control over relief supplies. But it can also prolong civil wars because of what is known as "aid taxation." This is a form of tax, paid by an aid agency to the side controlling the area, frequently by way of a percentage of the relief supplies, to gain access to the affected civilian population, which is then used to feed combatants.

Although the International Committee of the Red Cross (ICRC) has constantly reminded both sides in civil wars that they should abide by the rules of international law and make a clear distinction between civilians and combatants, this has rarely been heeded.

A World War II poster from the Pennsylvania State Council of Defense, printed between 1941 and 1943, emphasizes the primary idea of civilian protection: a locally based emergency response system designed to protect the general public.

Famous Civil Wars

There have, of course, been a host of civil wars over the centuries. England underwent three civil wars between 1642 and 1651 between the Parliamentarians (Roundheads) and the Royalists (Cavaliers) that ended with the execution of King Charles I and the declaration of the Commonwealth of England (from 1649 to 1653), which itself was replaced by the Protectorate, from 1653 to 1659, under the rule of Oliver Cromwell.

The American Civil War, which took place between 1861 and 1865, occurred following the election of Abraham Lincoln as president when seven southern states, in which slave labor was used, declared their secession from the United States and formed the Confederate States of America; these were closely followed by the remaining four states in which slave labor was used. Eventual victory for the North meant the end of slavery, but not until the death on both sides of some 620,000 soldiers and an undetermined number of civilians.

The Spanish Civil War, between Nationalists and Republicans, took place between 1936 and 1939, resulting in the establishment of a dictatorship under General Francisco Franco, which was to last for over 35 years. The Chinese Civil War was fought between the Chinese Nationalist Party and the Chinese Communist Party between 1927 and 1949, except for a brief period during the Second Sino–Japanese War when the two sides joined together to form the Second United Front. Once Japan was defeated in 1945, the two sides renewed the conflict until the Communists occupied the whole of mainland China, leaving the Nationalists in Taiwan.

Civilian Protection, Post-Conflict

United Nations peacekeeping operations have become one of the international community's primary instruments to assist countries in emerging from conflict and securing sustainable peace and stability.

This has not always been the case. The first 40 years of the organization's peacekeeping efforts were largely oriented toward keeping the peace between two sovereign nations that had been in conflict with one another. This was done largely through deploying peacekeeping operations with military components whose principal task was to supervise cease-fires and act as a buffer between those nations. With the end of the Cold War, however, conflicts between states began to decline as conflicts within nations increased. The levels and types of violence that characterized these conflicts were increasingly complex, states were often collapsed or on the verge of failure, and civilians were frequently displaced and/or threatened with physical violence. In response to this trend, the Security Council—the United Nations' organ responsible for the maintenance of international peace and security— began to authorize the deployment of multidimensional peacekeeping operations, designed to support the implementation of peace agreements and to set countries emerging from conflict on a path to sustainable peace.

Security Council Mandate

These multidimensional peacekeeping operations—operations made up of military, police, and civilian components—are generally deployed in the dangerous aftermath of a violent internal conflict, in which the physical security of civilians is often at risk. Recognizing that United Nations (UN) peacekeepers could have an important role to play in protecting civilians in these situations, the Security Council began to authorize peacekeeping operations with the mandate to protect civilians "under the imminent threat of physical violence." The first such peacekeeping operation (or "mission" in UN parlance) to have received this mandate was the United Nations Assistance Mission in Sierra Leone (UNAMSIL) in 1998. Since that time, 11 missions have received the protection of civilians mandate. In September 2012, there were eight peacekeeping operations authorized to protect civilians.

The Nature of Protection of Civilians Crises

Where modern, multidimensional peacekeeping operations are deployed, civilians often suffer disproportionately from physical violence. In some situations, civilians are caught in the midst of hostilities between two or more parties undertaking some military objective. This may lead to casualties among the civilian populations who have been unsuccessful in avoiding the hostilities taking place where they are living or gathered. Increasingly, however, civilians have become the direct targets of belligerents. They may be targeted by rebel groups that are looking to resupply or are interested in forcibly conscripting locals into their ranks. They may be targeted by groups wishing to achieve some psychological impact on a particular people, including through the use of sexual violence. In some cases, they may even be targeted by elements of the armed forces from the very government whose job it is to protect these civilians. Whatever the motivation, attacks on civilian populations have increased at an alarming rate over the past two decades.

Incidents in which civilians come under threat of physical violence can materialize rapidly and without warning and can degenerate into crisis situations with tremendous speed. These crisis situations can present enormous challenges for large peacekeeping operations, which often lack critical mobility assets required to respond quickly and decisively. Frequently, by the time a mission becomes aware that a protection of civilians crisis is unfolding, it may be too late to save lives or to intervene. For these reasons, the United Nations has been putting tremendous effort into developing policy, guidelines, and training for its peacekeepers, with the objective of helping them to prevent protection of civilians crises from arising in the first place. Rather than being forced to respond to crisis situations in which the lives of civilians may be at risk, peacekeeping operations with protection of civilians mandates are putting increasing focus on prevention, which is ultimately the best form of protection.

Analyzing Threats and Vulnerabilities

In order to prevent civilian crises from arising, peacekeeping operations must have a strong understanding of the threats and vulnerabilities of the civilians they are mandated to protect. While this would seem obvious, it is in fact an extremely challenging undertaking in the countries where missions work; these countries often have vast territory over which civilian populations are thinly spread, unforgiving terrain that makes ground movement extremely difficult, and undisciplined armed groups roaming the area with diverse and unsavory motives.

Understanding the various threats that civilians in a particular area may face, and their vulnerabilities to those threats, requires a sustained focus on situational awareness. Peacekeeping operations must utilize all of the tools at their disposal to obtain a comprehensive picture of the situation on the ground and analyze how the various factors that pertain may affect the physical security of the civilian population. The tools that peacekeepers can use to achieve greater situational awareness range from face-to-face communication with the local population to more advanced applications of technology that use satellite imagery to track potential perpetrators or map hot spots.

In any case, determining threats and vulnerabilities to civilians is a multidisciplinary effort involving the work of all components—military, civilian, and police alike. The military component, for example, can gain an understanding of the types of threats that civilians in its area of responsibility may face through its contacts with its counterparts in the national military structure, through talking to local populations during routine patrols, and through monitoring the movements of armed groups in the area. Likewise, United Nations police officers, who are often stationed in or near camps for refugees or internally displaced persons, can track the types of incidents that civilians in their areas have been facing. Civilians working in the operation, such as civil affairs officers, generally have strong contacts with the local authorities, who themselves have an intimate knowledge of the security issues facing civilians.

When peacekeepers have good situational awareness, they can prioritize the threats to civilians they wish to address. This prioritization will be based upon the likelihood that the threat will materialize, the types of violence the civilians may face, and the number of civilians likely to encounter the particular threat, among other things. Making decisions on which civilians to protect can be an extremely challenging endeavor, in both operational and moral terms, but protecting civilians must be undertaken on the basis of a strong understanding of the threat landscape and a corresponding analysis of how those threats are likely to affect civilians.

Managing Protection Crises Once They Arise

Often, in spite of a peacekeeping operation's best efforts, protection of civilians incidents can arise without warning, or without sufficient time for the mission to react in a way that would eliminate the possibility of the loss of civilian life. In extreme cases, these incidents can degenerate into major crisis situations, where the risk to civilian lives can climb to alarming proportions. Although every situation requires a different response, oriented to the particular circumstances, there are certain elements of addressing protection of civilians crises that are essential for peacekeeping operations to engender.

Most important, the response to a protection of civilians crisis must be a whole-of-mission effort. By the time a situation has escalated to crisis proportions, in which civilians are already being killed, military intervention from a peacekeeping operation alone will likely not be sufficient to bring it under control. While a show of force from the United Nations is an important deterrent measure, missions must also use the political levers at their disposal to deescalate the violence.

Critical in this respect is the political advocacy of the head of mission, usually designated as a special representative of the secretary-general, who must work with her or his government counterparts to call for a halt to the violence. This can be an extremely difficult task for the special representative. It is not infrequent for groups affiliated with the government to be involved in the violence in some way, however oblique. In situations in which those groups may have helped the government to come to power or fend off a putsch, the government may be less willing to discourage them from engaging in violence, much less threaten to hold them to account for any crimes committed during the violence.

In other cases, the host government simply may have the will to respond, but may lack the capacity to do so in a timely or efficient manner. In the contexts in which peacekeeping operations are deployed, governments are often in the process of rebuilding and are focused on the most basic governmental operations as they put in place the national, state, and municipal infrastructure. In these situations, missions are sometimes required to act independently to protect civilians. In others, peacekeeping operations can provide important support to their government counterparts to address protection of civilians crises.

Protecting Civilians in South Sudan

The response of the United Nations Mission in South Sudan (UNMISS) to a protection of civilians crisis in Jonglei, in what is now South Sudan, that began in late 2010 and unfolded over the first half of 2011, is a good illustration of how a peacekeeping operation can effectively engage the government to protect its civilian population.

In late 2010, members of the Murle tribe conducted a number of small-scale raids against the Lou Nuer tribe, during which hundreds of cattle were stolen, dozens of people killed, and several women and children abducted. Tension mounted in the Lou Nuer community, who sought revenge for what they viewed as Murle aggression, as well as the government's failure to protect them. More than 1,000 Lou Nuer attackers organized and marched into Murle territory, burning villages and killing hundreds. Murle raiders then launched an attack on a string of villages in Lou Nuer territory, including a village home to a Lou Nuer "prophet" who was accused of organizing many of the raids.

The mission recognized the likelihood of a reprisal attack by the Lou Nuer and took action to prevent further violence. This took place along multiple tracks, including political action by the special representative of the secretary-general, who lobbied the government to recognize the scale of the issue and take appropriate action. For its part, the mission deployed a number of integrated (military, police, and civilian) teams to hard-to-reach areas to gather information, and sent multiple air reconnaissance flights to survey the landscape from above and determine the position of forces on the move. As it became clear that an attack was imminent, UNMISS also deployed a number of military units to the area to deter the attackers.

From the outset, the mission recognized that it alone could not hope to prevent another attack. The number of attackers involved would likely be too large, and the area too vast, and the primary protection responsibility belonged to the government. However, the government's military and police forces lacked the logistical capacity to move across Jonglei's swampy terrain (South Sudan is home to some of the world's largest floodplains). The mission's military and police, along with the South Sudan Armed Forces and South Sudan police, developed a plan to deploy government military and police at strategic crossing points between Lou Nuer and Murle territory. The mission supported the logistical deployment of government forces to these areas so that they could respond.

Given the range of challenges in addressing this crisis (UNMISS was a new mission and only deployed at a fraction of its mandated strength, the number of Lou Nuer attackers that eventually marched on Murle territory grew to around 5,000 people, air assets were limited, the overland terrain was extremely difficult, etc.), additional civilian casualties did occur. UNMISS's action, however, in conjunction with the government of South Sudan, was able to provide a degree of protection for civilians caught in the fighting. Additional civilian lives would undoubtedly have been lost had the mission not undertaken a number of concerted, multidimensional efforts in support of its mandate to protect civilians from the imminent threat of physical violence. The mission's response to this crisis provides a good example of how all of the tools at a peacekeeping operation's disposal can be leveraged to protect civilians, notwithstanding the massive challenges that it inevitably faces in this endeavor.

Classification of Systems

A system is an organized collection or arrangement of elements that control and distribute resources such as energy and information in order to achieve some result. Systems generally involve multiple inputs and outputs, may involve feedback loops, and, in general, are resistant to simple, linear solutions to problems. In the last 50 years, systems thinking has become common in many professions, from basic science to applied engineering, and professions such as systems design and systems analysis have been developed to meet this need. Systems thinking is particularly useful when trying to understand the workings of complex processes, whether they relate to the economic functioning of a country, the operation of a hospital, or the functioning of a business, when decisions must take into account the interactions of many separate systems and when the consequences of a single action may be felt across many systems.

Different Ways to Classify Systems

There are many different ways to classify systems: open versus closed, static versus dynamic, natural versus human-made, etc. Of course, a system may be classified along several dimensions, and few systems created by people are purely one type of system only, but thinking through the different types of systems involved in any enterprise can help develop plans for operations, including plans to respond to emergency or disaster situations.

A closed system has no significant interactions with its environment; one example is a chemical reaction in a closed glass container. The results of interactions within a closed system are deterministic and can be predicted from initial conditions. An open system, in contrast, interacts with its environment, allowing information, matter, and energy to cross its boundaries; examples of open systems include business organizations, ecological systems, and plants. A static system such as a bridge has structure but not activity, while a dynamic system such as a school has both structure and activity. Of course, any system is static only in a limited frame of reference: although a bridge does not move, it is constructed and will break down over time, both dynamic processes; in addition, it may be deliberately altered or maintained, both dynamic processes.

Natural systems are created through natural processes and have a high degree of order and equilibrium; examples include the food chain and the natural water cycle. Elements within a natural system adapt to their environment and to events within it, and materials are continually recirculated; natural systems survive if they adapt to changes in the environment; those that do not become extinct. Human-made systems are relatively recent in origin, as the rapid development of technology has multiplied the impact of modern humans on the environment. Human-made systems often produce unintended consequences; for instance, the construction of the High Aswan Dam on the Nile River achieved its goals of producing hydroelectricity and controlling flooding, but also produced negative, unanticipated consequences, including harming the fishing industry, increasing erosion in the Nile Delta, and fostering epidemics of bilharzia along the Nile. A systems view would have taken into account the side effects of the dam's creation and might have come up with a better solution or mitigated the problems.

Classification of Systems for Recovery

The normal functioning of any organization may be disrupted for any number of reasons, including natural disasters (e.g., a flood or tornado), equipment failures, human error, and acts of malice (e.g., computer hacking, arson). The key to a successful disaster recovery plan is focusing on how to best resume normal activities after the disruption and making preparations to respond to the common elements in how any disruption might affect the unit (e.g., loss of information, loss of equipment, loss of personnel), rather than creating a separate plan for each type of potential disruption.

One type of classification that is useful when planning for or responding to an emergency or disaster situation is the classification of systems as critical, essential, necessary, or desirable. Going through the process of classifying the systems in any enterprise, whether it is a business or a relief effort, helps set priorities so that effort and resources can be directed efficiently and the most important systems restored first.

To take a practical example, Michigan State University has published guidelines to assist different units of the university in developing a continuity of operations plan (COOP) as a tool in planning for and responding to disasters or incidents that severely disrupt normal operations. Part of the process of creating a disaster recovery plan for a unit is conducting an impact analysis for all functions of the unit, based on their criticality. Activities are classified according to the time they can remain interrupted: "critical" activities can remain disrupted for less than one day, "essential" activities can remain interrupted for two to four days, "necessary" activities can remain disrupted for five to seven days, and "desirable" activities can remain interrupted for 10 days or longer.

Functions of each unit are also classified in three other ways. First, they are classified according to whether they depend on the availability of specific resources of the university (e.g., the mainframe computer system, the telephone network, paper records) and their degree of dependency on each resource (high, medium, or low). Second, systems are also classified in terms of what would be impacted if they were not performed: human life, federal funding, students, operating efficiency, laws broken, and reputation. Finally, for systems that generate revenue or receive external funding (e.g., federal grants), it must be specified how much and which revenue would be lost were the function not performed for different time periods (1 hour, 1 day, 2 days, 3 days, 1 week, 1 month) and how much additional cost would be incurred if the function were not performed for each time period (e.g., loss of funding, fines). Finally, functions are ranked numerically, with critical functions receiving a score of 1 (i.e., they should be the first priority), essential functions a score of 2, necessary functions a score of 3, and desirable functions a score of 4 (i.e., they are the last priority).

Susan Snedaker provides a system for classifying systems within a company, using similar categories as those provided in the Michigan State guidelines. In Snedaker's system, a category 1 or "critical" system is mission critical, meaning that the system must be present for the company to remain in business, and the goal to restore this system to functioning following a disaster would be expressed in hours rather than days. A category 2 system is considered "essential," not so much for immediate functioning as for long-term operations; for instance, in a business the payroll system might be classified as essential. Category 3 or "important" functions are required for the business to function at top efficiency and would disrupt the business if they were lost for days or weeks, but are not so critical to be restored immediately; examples might include e-mail and Internet access. Category 4 or "minor" functions will not be missed in the short term, although they may make it easier for the business to deal with some relatively small issues; the process of classifying systems for disaster planning may also identify minor functions that are no longer needed by the business and can be dropped.

The Health and Human Services Disaster Recover Leadership Network for Pinellas County (western Florida) provides guidelines for health and human services providers to prepare for a disaster; their focus is on preparing so that high-priority human services (including the provision of shelter, food, and medical assistance) will be available as soon as possible after such a disaster. Although the terminology is sometimes different, the approach to planning is similar to that recommended in the two classification systems already discussed—list the functions provided by an agency or provider, evaluate them in terms of the consequences if they were not performed, and prioritize them so that after a disaster, resources can be directed to the functions that are most immediately critical.

The first step in the network's guidelines is to conduct a vulnerability analysis, dividing vulnerabilities into three categories: impact on humans (including staff, clients, and community reputation), impact on property (including records and electronic databases as well as physical facilities and supplies), and impact on agency operation (likelihood of essential functions being performed following a disaster; for example, if electricity were shut off or normal means of transportation were not available). Vulnerabilities can exist in six major categories: location (e.g., access to major roads and bridges), finances (e.g., fluidity of cash flow, availability of additional emergency funds), communications (e.g., phone network, emergency communications equipment), facility (e.g., conditions of buildings, availability of space to shelter staff and/or others), daily resources (e.g., vehicles, computer equipment), and disaster resources (e.g., availability of generators, number of staff trained in first aid and CPR).

To assist an organization in identifying vulnerabilities, the network suggests using a worksheet in which different threats (e.g., hurricane, cyber attack, terrorism, disease epidemic) are evaluated in terms of the impact on humans, property, and operations, and the strength of internal and external resources to respond to the threat. The degree of impact is quantified on a scale from 1 to 5, with higher numbers signifying more impact; for instance, 1 is described as "minor; agency operations not affected," while 5 is described as "catastrophic; critical systems off-line for extended period; data lost or irreparably corrupted; public health and safety affected." The strength of resources available is also evaluated on a scale from 1 to 5, with 1 signifying that resources are strong and easily available and 5 signifying resources are weak and difficult to find even outside the disaster area. The totals for each type of disaster are summed, and higher totals indicate greater vulnerability.

The network also provides guidelines for classifying functions in terms of “essential” or “not essential”; essential functions include providing food, water, information, counseling, clothing, shelter, and medical care. Agencies then make a list of essential functions, prioritized to indicate which functions should be restored within 24 hours, which within one week, and which within one month. To determine which functions are most important to restore quickly, the network provides a series of questions addressing the consequences if that function were *not* restored within the specified time period, the probability that demand for that function will increase following a disaster (for instance, the need for temporary shelter would be expected to increase after a tornado), which resources would be needed to sustain a given function, and whether less essential functions could be suspended or moved in order to concentrate on more essential functions.

Climate Change Adaptation

Climate change adaptation refers to the need to adapt to the future climatic conditions that will affect all regions of the world in order to minimize the impact of disasters associated with climate change. Ever since Earth formed 4.4 billion years ago, climate change has occurred. Several factors contribute to climate change, including the distribution of the continental plates, height of mountains, and cyclic changes in Earth’s orbit around the sun. Natural mechanisms have contributed to climate change during the Quaternary Period (roughly the last 2.4 million years), with particular scientific interest in the Holocene epoch (the last 12,000 years).

Human (anthropogenic) activities are contributing to climate change, such as vehicle emissions, industrial plants, and land use practices. However, adaptive strategies can be employed to prepare for future climate change. The Norse settlement of Greenland during the Medieval Warm Period (MWP) and later abandonment following the onset of the Little Ice Age (LIA) provides an example of past adaptation to climate change in the Arctic.

Combined, natural and anthropogenic forcing mechanisms of climate change are placing people at great risk from climate-induced disasters. Historically, the majority of natural disasters are caused by climate-related events: hailstorms, snowstorms, extreme cold, tornadoes, hurricanes and typhoons, monsoon rains, heavy rains, high winds, avalanches, rock slides, mudslides, drought, wildfires, and infestation by vectors (insects). With climate change, many of these types of events will occur with greater frequency and intensity, placing the lives of people who live in areas impacted by these disasters at increasing risk.

Coastal flooding in Narragansett, Rhode Island, April 2007. Increases in atmospheric carbon dioxide are projected to cause Earth to warm by 6.1 degrees C from now to between 2060 and 2090, similar to the last interglacial period, between 125,000 and 115,000 years ago. That period experienced a significant sea level rise, one of the concerns of scientists who predict adverse effects of climate change. A similar sea-level rise in the coming years would cause severe flooding of coastal cities and even submerge low-lying islands.

Celestial Mechanics

The astronomical theory developed by Milutin Milankovitch in the early 1900s is widely accepted by climate scientists as the best theory for explaining changes in the seasons, as well as climate change over hundreds of thousands of years. Milankovitch identified seasonal and longer-term systematic variations in Earth's orbit around the sun based on meticulous measurements of the positions of stars and equations that explained how the gravitational pull of other planets and stars affected Earth's orbit. Through his calculations, Milankovitch identified three primary celestial mechanisms that affect long-term cycles of cooling and warming on Earth, including eccentricity, precession of the equinox, and obliquity.

Eccentricity refers to a systematic shift in Earth's orbit around the sun from an ellipse to a circular pattern and back to an ellipse every 95,000 to 136,000 years, averaging 100,000 years. When Earth's orbit is circular, its distance from the sun is relatively steady throughout the year, minimizing extreme seasonal variation. When Earth's orbit is eccentric, seasonal variation in temperature is more extreme. In an eccentric orbit, the Earth is closest to the sun at perihelion and farthest from the sun at aphelion. If perihelion occurs during Northern Hemisphere's summer, this accentuates the length and intensity of the summer season. If aphelion occurs during Northern Hemisphere's summer, the season is shorter and less intense.

Precession refers to a wobble of the Earth in its orbital path around the sun that occurs every 19,000 to 23,000 years. This wobble affects the point when Earth's orbit is nearest the sun (the location of perihelion) and shifts from the Northern to the Southern Hemisphere approximately every 9,500 to 11,500 years. Obliquity refers to cyclic changes in the angle of the Earth relative to its rotational axis around the sun. The obliquity varies over a roughly 41,000-year period from 22 degrees to 24 degrees, 6 minutes. Changes in Earth's axial tilt result in cyclic changes in the length and intensity of the seasons.

Case Study: The Norse Settlement and Abandonment of Greenland

Multiple lines of evidence (historical documents and archaeological records) indicate the Norse settled Greenland around 985 c.e., during the MWP when the Arctic was warmer than present. Although there is still some dispute about the geographic extent of warming associated with the MWP, most scholars agree that North Atlantic water was approximately 1.8 degrees F (1 degree C) warmer than present for the period spanning ca. 900 to 1250 c.e. The warmer water melted the northern ice packs, making the North Atlantic easier and safer for exploration and navigation.

In their synthesis of Icelandic and Norwegian historical documents, Paul Buckland and his coauthors found documentation indicating that Norse farmers first settled Einarsfjörður, the modern area of Igalikup Kangerlua, located in the extreme southeastern reaches of Greenland, in roughly 985 c.e. Norse settlement of Greenland was led by a Viking explorer commonly known as Eric the Red.

The landscape of Greenland is harsh, and the climate harsher. To survive, it was essential for the Norse settlers to adapt to the severe climatic conditions of the region by modifying the landscape so that it would support crops, and to rely increasingly on sea mammals for protein. The Norse needed to grow enough hay during the short summers to feed their cattle, sheep, and goats through the long, cold winters. The feed needed to be of adequate quality to keep the livestock healthy enough to breed successfully and to provide milk, meat, and hides to the settlers. According to archaeological investigations, to grow adequate crops for their livestock, the Norse implemented agricultural technologies that had been used in their homeland of Norway. They cleared the land of native vegetation, developed water control projects with dams and irrigation networks, and fertilized the soils by spreading a combination of human and animal waste on the fields.

Despite the agricultural ingenuity of the Norse, the harsh climate of Greenland required additional adaptive measures be adopted. Faunal remains recovered from archaeological sites show a dependence on caribou, fish, and sea mammals to supplement the farm diet. Chemical analyses of the skeletal remains of buried Norsemen indicate that during the MWP, the Norse modified their diets to become less reliant on livestock and crops and to become more reliant on fish and sea mammals. The skeletal studies indicate that during the initial period of Norse settlement, marine sources provided 20 percent of the diet. During the final decades of Norse settlement, marine sources provided 80 percent of the diet. The change in diet is in part attributed to degradation of the land and loss of arable land to sea level rise (geologic evidence indicates that for the past 3,000 years, Greenland has been rapidly subsiding). Susanne Lassen and coauthors speculate that the Norse became increasingly dependent on marine animals because the climatic conditions were conducive to supporting a strong population of seals. Through their examination of marine plankton in sediment cores recovered from the Arctic Ocean, Lassen and colleagues determined that there were high wind conditions later in the MWP, which resulted in mixing of the near-shore surface water, which increased nutrients needed to support fish and marine mammals.

Lassen and coauthors also speculate that high winds during the late MWP kept the Norse from developing an economy that relied almost exclusively on intensive fishing of the fjords. The increased winds would have made the seas more treacherous, increasing the risk of losing or damaging boats and potentially resulting in the loss of fishermen's lives. In contrast, seal hunting could be undertaken onshore or near shore and thus posed less risk to the boats and lives of the Norse, and hence this is the strategy they adopted.

Although the timing of the demise of Norse settlement on Greenland is uncertain, historical documents and the archaeological record indicate the land was abandoned in the early 1400s. Many scientists and historians speculate that abandonment occurred as a result of increasingly colder and harsher conditions, as well as a return of sea ice to the fjords. Paleoenvironmental reconstructions indicate that by 1450 c.e. there was a significant increase in sea ice and a marked reduction in the marine food supply. These conditions, combined with a loss of arable land due to subsidence, would have made survival on Greenland extremely difficult. Although historical, social, and political factors also likely contributed to the Norse abandonment of Greenland, paleoenvironmental and archaeological evidence indicates that a rapidly cooling climate, increased sea ice, and a reduction in available marine resources were important factors contributing to the Norse abandoning Greenland.

Solar Cycles

Solar cycles refer to changes in the number and intensity of sunspots, which are caused by the differential rotation of the sun. According to David Hathaway, the sun's poles rotate slower than the sun's equator, causing its magnetic field to become distorted and twisted over a period of years. Distorted magnetic lines within the sun twist like rubber bands and eventually break through the visible surface of the sun and are commonly referred to as sunspots.

The number of sunspots observed on the sun's surface varies from year to year, following an 11-year cycle referred to as the Schwabe cycle. A 22-year cycle is referred to as the Hale cycle. There are also lower-amplitude cycles referred to as Grand Maxima and Grand Minima. These cycles may range from 70 to 300 years and are believed to have affected some of the more significant short-term climate cycles on Earth. For example, the MWP (ca. 950–1250 C.E.), is believed to have been caused by a Grand Maxima cycle. In contrast, the LIA (ca. 1450–1850 C.E.) is believed to have been caused by a Grand Minima cycle.

The impacts of the MWP and LIA on people were considerable, causing changes in where agriculture could be practiced, as well as changes to the fishing industry and other economic activities. Since around 1900 C.E., the amplitude of the sunspot cycle has been higher than it was for the preceding five centuries, indicating that the sun is now in a Grand Maxima cycle similar to the MWP. Today, however, unlike the MWP, human activities are accentuating climate change and making future climate conditions more unpredictable.

Anthropogenic Causes of Climate Change

For several years, many scientists have argued that greenhouse gases (GHG) from anthropogenic emissions (e.g., industry and vehicles) and land use practices (e.g., deforestation and agriculture) have contributed to climate change during the past century. To better understand how people affect climate, in 1988 the United Nations Environment Programme (UNEP) and the World Meteorological Organization (WMO) formed the Intergovernmental Panel on Climate Change (IPCC). This organization was formed to review and summarize climate studies that analyze the effects of anthropogenic GHG emissions, including carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O) and various chlorofluorocarbons (CFCs), and human land use on climate change.

The IPCC reports indicate that anthropogenic emissions of CO_2 are increasing the percentage of CO_2 in the atmosphere. To understand how this increase in CO_2 will affect future climate, the IPCC developed climate models. Although the IPCC climate models have not yet been perfected, these increases in CO_2 are projected to cause Earth to warm by up to 6.1 degrees C from now until between 2060 and 2090. Warming of this magnitude is similar to conditions that occurred during the last interglacial period, between 125,000 and 115,000 years ago. Sea level during this period was approximately 5 meters (16 feet) higher than at present—a level that would result in devastating flooding of major coastal cities and the complete inundation of low-lying islands.

In addition to direct impacts on coastal cities, estuaries, beaches, and cultural sites, warming of the magnitude predicted by the IPCC has the potential to effect changes in atmospheric and oceanic circulation, resulting in more intense storms in some regions and drought in others. Changes in atmospheric and oceanic circulation will also affect the distribution of arable lands and the distribution of shellfish, fish, and other marine organisms that people rely upon for food. The IPCC panel predicts devastating effects to the world economy as a result of stresses to global food and potable water supplies, and social and political stresses associated with the need to relocate millions of people from coastal communities and low-lying islands.

Conclusion

Climate change poses a significant threat to human populations worldwide. Studies of past climate change clearly indicate that cycles of warming and cooling are driven by driven by natural forcing mechanisms. The amplitude, timing, and extent of natural climate change to a large degree are driven by changes in Earth's orbit around the sun and changes in the intensity and duration of sunspot cycles. For generations, people have adapted to climate change by adopting new technologies, moving to newly opened landscapes after glaciers retreated, and moving from areas that were no longer habitable due to any number of factors (e.g., prolonged drought, glacial advances, sea level rise). The case study on the Norse, included in this article, provides an example of how humans have adapted to climate change in the past. The Norse migrated to Greenland during the MWP, a period when the Northern Hemisphere was as warm as or warmer than present, and the arctic seas were open for exploration. At the onset of the LIA, they left Greenland because they could no longer sustain their families.

Current climate change in many ways replicates the conditions of the MWP. Whether current conditions are being driven by anthropogenic or natural forces is still debated among scientists, but most scientists agree that climate is changing. People can perhaps learn from the Norse, that flexibility may be required to adapt to the shifting landscape—although we may live along beautiful coastlines now, in the future these coastlines may be inundated by seawater. To adapt, we must move or build barricades to keep the sea at bay. The key to adaptation, however, is understanding how climate change may impact an area in the future and recognizing the power of nature and the need to adapt to its forces.

Cluster

The word *cluster* stands for congregation, or grouping of people or organizations coming together around a specific interest to be fulfilled in a joint manner. Considering this definition, the word *cluster* in disaster and crisis management refers to a field of specialization around which multiple actors (governments, international nongovernmental organizations (INGOs), the International Federation of Red Crosses and the Red Crescent Movement, and the United Nations (UN) agencies) operate. The idea of operating in a joint manner in both disasters and complex emergencies by unifying efforts, resources, and expertise is known as the cluster approach.

Background, Aim, and Scope

The cluster approach is one of the fields of intervention that came about as a result of reform in the humanitarian sector in 2005 by the Inter-Agency Standing Committee (IASC). In particular, IASC—together with other organizations—decided to implement a mechanism through which international and national agencies could improve their response to disasters and complex emergencies in support of the affected governments. Past experience, such as the 2004 and 2005 Darfur crisis, in conjunction with the evaluation of the humanitarian response, carried out by the Humanitarian Response Review (HRR) on the behalf of the emergency response coordinator (ERC), highlighted the inadequacies of collaborative efforts in certain sectors (shelter, water and sanitation, etc.). Thus, the aim of the cluster approach is to improve preparedness, avoid duplication of efforts, improve the accountability and the quality of humanitarian services, better coordinate the efforts of the humanitarian sector, and strengthen its predictability.

Preparedness refers to the ability of the international system to respond to more than one emergency per year. For instance, IASC established that each cluster should be able to respond to three emergencies per year, two of them happening simultaneously, with provisions of service for 500,000 beneficiaries. One of the most important characteristics of the cluster approach is predictability. Predictability refers to the ability of the cluster to fill the gaps in the humanitarian sector at a global as well as at a country level. One important characteristic of the cluster is that of being a "provider of last resort." This means that when there are gaps that cannot be filled by the entire international community, the cluster lead will step in to take care of it. If this is not possible due to a lack of financial resources, the cluster lead is still obliged to make an appeal to meet the specific need. Thus, the strategic relevance of the cluster approach is that it favors collaboration, making cluster members equal partners. In the past, strategic response in emergencies was based on a first-come, first-served basis; now the system is aimed at improving predictability.

Cluster Structures

The cluster approach consists of nine clusters created on the basis of identified needs and, therefore, services to be provided. In particular, the identification of specific clusters/sectors over others has been done on the basis of those sectors experiencing difficulties in coordination and accountability. Sectors at a satisfactory level of accountability and coordination have already been achieved, such as the agriculture sector, led by the Food and Agriculture Organization of the United Nations (FAO); the food sector, led by the World Food Program (WFP); the education sector, led by the United Nations International Children's Fund (UNICEF); and refugee welfare, led by the United Nations High Commissioner for Refugees (UNHCR). These are not included in the global cluster.

Clusters can be grouped into three main areas: technical, cross-cutting, and common services. Each cluster is paired with an agency that is the cluster leader. The cluster or sector lead does not necessarily have to be assigned to a UN agency and can be entrusted to any organization. For instance, the International Federation of Red Cross (IFRC) shares the lead of the emergency shelter cluster with UNHCR. The IFRC leads the cluster in case of natural disaster and the UNHCR leads in case of conflicts. The following is a list of areas and related clusters:

1. Technical areas:
   - » Nutrition (UNICEF)
   - » Health (WHO)
   - » Water/sanitation (UNICEF)
   - » Emergency shelter (UNHCR for conflicts); in case of natural disaster (IFRC).
2. Cross-cutting areas:
   - » Camp coordination and management (UNHCR for conflicts; IOM for natural disasters)
   - » Protection (UNHCR for conflicts; UNHCR/OHCR/UNICEF in case of natural disasters)

    - Early recovery (UNDP)
3. Common service areas:
    - Logistics (WFP)
    - Emergency communications (OCHA/UNICEF/WFP)

The cluster approach operates at two levels: global and local/country level. The above list of clusters is generally transposed at a local level as well. Global and local/country-level clusters fulfill different tasks. At the global level, the cluster works to build global capacity; at the country level, it is focused on building relationships with local actors, such as governments, NGOs, grassroots, and citizens.

In particular, the global cluster lead covers three main areas: standards and policy setting, building response capacity, and operational support. The global cluster lead's work within the area of standards and policy setting is related to the development or improvement of standards and their dissemination. Response capacity is achieved through maintaining surge capacity, standby rosters, and material stockpiles. Finally, the global cluster leads are also responsible for the provision of operational support, a task accomplished through long-term planning; human, financial, and capacity needs assessment; and advocacy.

Country cluster leads are tasked with information management and operational support of the coordination mechanisms, which are implemented through the 3Ws: who, what, and where. The creation of such a mechanism makes the identification of organizations and of the structures of the whole response system easier. At the country level, it is important to understand who takes the lead for each sector.

In term of accountability, the global cluster leads report to the emergency response coordinator (ERC) operating through the Office for the Coordination of Humanitarian Affairs (OCHA). All the clusters are directly accountable to the humanitarian coordinator (HC), who in turn is accountable to the ERC. The only exception to this system of accountability is the IFRC, which is a "convener" rather than a cluster lead.

Cluster Activation and Closeout

The activation of the clusters occurs when the emergency and complexity of an event require the intervention of multiple international organizations, gaps in the humanitarian needs pointed out by governments and cluster agencies or as a result of consultation among the resident and humanitarian coordinator (RC/HC) and the country team members. Cluster activation is a "six-step process" resulting from consultation among the HC, ERC, cluster leads, hosting governments, and relevant IASC partners at the country level. The humanitarian coordinator provides the ERC with analysis of the gaps and recommends a specific cluster in the country. The ERC then consults with global cluster lead agencies, giving them 24 hours to respond before activation is approved. Subsequently, the ERC informs the IASC of new developments and ensures that appropriate guidance and support are provided. Finally, although there are 11 global clusters, this does not mean that an emergency will require the activation of all of them.

There is no clear guidance on when and how a cluster should end its activities.

Cognitive Novelty, Engaging in

There are several pitfalls and saving graces in studying how to engage in cognitive novelty: that is, either the processes by which new and useful ideas are generated or the impression that the situation presented to a decision maker is novel. Particular attention is given to the role of computer-based systems in this process (or, perhaps more precisely, the role of the task and how it is packaged and presented via a computer-based system). There are important perspectives on processes for negotiating the development of the task and its computer implementation.

In crisis management, the need to engage cognitive novelty arises in many situations. In crisis planning, it is frequently desirable to generate unplanned-for scenarios (i.e., highly nonroutine but plausible crisis scenarios) as a prelude to identifying how they may be addressed. Similarly, in crisis response, situations on the ground rarely match exactly those encountered in planning or training exercises. It is therefore desirable for response personnel to be able to generate new and useful ideas—often under tight time constraints. Development of the skills for addressing this need may occur in the field, but also in training situations.

The highly skilled decision maker—whether coming from jazz improvisation, firefighting, or field medicine—is remarkably adept at confounding attempts to draw broad conclusions from his or her novel behaviors. Presented with a novel situation (i.e., one that is not covered by a standard operating procedure), the decision maker may create a new solution, which is then implemented and evaluated. When these solutions are presented to implementers or evaluators to be executed, some degree of learning may be required, in which implementers or evaluators (such as training personnel) attempt to discover how the proposed solution might be executed and validated in the real world. In order to streamline the training process, training programs in crisis management increasingly rely on computer-based systems to provide feedback to trainees, as occurs in gaming simulations.

The inclusion of computer-based systems in training creates considerable challenges when one of the training goals is to engage cognitive novelty. As finite-state machines, computer-based systems are not designed for "out of the box" reasoning. Accordingly, research in cognitive science and artificial intelligence has been concerned with developing computational approaches to interpreting and evaluating novel ideas created by human operators. Similarly, gaming simulations in crisis training are slowly becoming more adaptive and thus capable of generating novel scenarios with little human intervention.

To understand the dynamic tension between human and computer in this context, it is useful to introduce the concept of engagement: participants' utilization of their attention, effort, and knowledge in undertaking the task set before them. The domain of the participants in emergency response operations stirs up some very human dichotomies: heroism/cowardice, life/death, truth/lies—not merely in the general population but also in the participants themselves. It is not unreasonable to expect that systems seeking engagement must reflect designers' understanding of the domain (if not their actual experience in it) if such systems are to be successful.

A process for negotiating the development of the task and its computer implementation may begin with identifying elements of the task, the environment within which it is presented, and the participants that foster engagement. In research on emergency response, for example, time constraint and variable levels of emergency event severity may be highly salient—and thus key elements to include in a simulation. Other possible factors include commitment to decision (i.e., a situation where decisions cannot be "undone"). The environment for delivery of the task may also foster or hinder engagement. Participant background and expectations are likely to dictate, ultimately, whether engagement is achieved. Indeed, it is often worthwhile to examine whether participants are positively inclined to engage the task. Such an assessment may be made by considering whether they view their performance as tied to their feelings of self-efficacy or to other incentives.

Cold Site

A cold site, also known as a "shell site," is a designated standby recovery facility (a warehouse, an empty office building, or a similar construction) large enough to host the mission-critical activities and applications of an organization's primary site. It is essentially a reserved maintained space (raised floors with electricity, air conditioning, humidity controls, fire protection, and pre-installed wiring) ready for the installation of workstations, office equipment, and networking and computer systems that will be shipped in the event of a primary site outage.

As a cold site does not come set up with hardware, software, or backed-up versions of the organization's data, it requires minimal start-up costs. Vendors offer cold site services on an annual subscription fee that includes access to the facility and, in most cases, two one-day disaster recovery tests. Although this is a less expensive site recovery strategy, it should be noted that it also takes some extra time to get the organization's systems up and running after the outage because new systems have to be installed. Normally, the organization should expect full recovery of its work environment within 48 hours from disaster declaration, making this solution more suitable for organizations that can sustain a few days of downtime before business resumption and for those that, following a major disaster, lose their primary site for quite a long time. A further limitation of cold sites is that the testing of the service can become very expensive because it cannot take place unless all equipment and systems are expedited and communications lines installed and configured according to the organization's needs. Equipment and systems must be temporarily rented or leased and then, at the end of the test, returned to their owners. Alternatively, they can be sourced from the primary site, but this solution may cause disruption to the business (unless a test is run on nonworking days, for example, during a weekend) and transportation to and from the cold site increases the risk of damage.

Cold site service vendors may have multiple subscribers contracted to use their sites. In the advent of a widespread disaster, only one of these will be able to relocate in every site. It is therefore important that the organization require the vendor to clearly state in the contract the limits on the number of clients from the same geographical area entitled to use the cold site services offered. The organization may also consider including a "no lockout" clause in the contract, something that, on one hand, will increase the cost of the service but, on the other hand, will guarantee a cold site even in periods of high demand.

An attractive alternative to a cold "shell" site service is the use of mobile sites or "porta-sites." In this scenario, self-contained trailers or other easily relocated units equipped with the appropriate environmental controls, electrical generators, and telecommunication systems are transported to the primary site so that equipment can be obtained and installed near the original location. Business continuity plans should reflect how long it will take for the mobile site to be set up and running in the disaster location and all pre-configurations required for this. The service usually costs the same as a cold site but brings the work environment to the end user, thus saving travel time for the recovery personnel and offering greater flexibility to organizations with multiple sites nationally and internationally. An additional advantage this option offers is that it makes testing more feasible. Mobile sites may also be configured to offer "warm" or "hot" site recovery services.

Collaboration

Since the 1940s, crisis management has been evolving from a top-down bureaucratic model toward a more collaborative system. One important feature is that, instead of a command or control system, collaboration brings a more dynamic and flexible network model that facilitates multiorganizational, intergovernmental, and intersectoral cooperation. Dynamic and efficient strategies have been adopted in the field of crisis management to replace hierarchy and standard procedures. Another feature is the changed relationship between government, nonprofit organizations. and the private sector. Calls for open communication and broad cooperation dispel the authoritarian air that long hung over the field of crisis management. Nonprofit organizations and the private sector take shared partnership and responsibility along with the government. They support, coordinate, and interact with each other; they also provide and receive information and all types of assistance from each other before, during, and after a disaster.

Collaboration is essential in addressing both natural and human-made disasters. In the management and coordination of disaster preparedness, response, and recovery, governments need to work closely with nonprofit organizations and the private sector. Citizens should also be included in the entire process. The National Fire Protection Association (NFPA) of the United States 1600 and the Emergency Management Accreditation Program (EMAP) standards define emergency management programs as "a jurisdiction-wide system that provides for management and coordination of prevention, mitigation, preparedness, and response and recovery activities for all hazards"(EMAP Standard 3.3.3). The standard also requires an advisory committee to "ensure that the program is developed and maintained in collaboration with program stakeholders, both from policy and operational levels" (EMAP Standard 4.3.2). The president; Congress; federal, state, local agencies; nonprofit organizations; the private sector; and individual citizens are all stakeholders of emergency programs in practice.

Generally, intergovernmental collaboration, public-nonprofit collaboration, and public-private collaboration are the three most usual patterns of collaboration.

Intergovernmental Collaboration

Federal, state, and local agencies share the responsibility of crisis management when facing a disaster. Different levels of governments need to work with each other toward an effective and efficient crisis management system. Interstate collaboration is also necessary in some cases.

Since the 1940s, with the start of the Cold War, the U.S. federal government has been increasingly involved with state governments in crisis management. By that time, the Federal Disaster Act and the Civil Defense Act were passed, and the Federal Civil Defense Administration was established to provide assistance during disasters. Natural and human-made disasters during the 1960s and 1970s, such as the 1964 Alaska earthquake, increased the demands for comprehensive disaster management. Actually, the federal government was not involved in the costly phase of disaster response work until the 1964 Anchorage, Alaska, earthquake. Executive Order 12127 established the Federal Emergency Management Agency (FEMA) comprising several federal agencies, to provide broader disaster management and comprehensive assistance to local communities. For most federal assistance during disasters, a Presidential Disaster Declaration is required, which initiates mechanisms for collaboration and use of all-level government resources. Federal assistance includes individual and public assistance, but mostly it serves as a source of funding. In some cases, federal departments and agencies can provide immediate lifesaving assistance to states without a formal presidential declaration.

State governments usually play the role of intermediaries. They assist in federal policy implementation, local community training, and federal grant funneling. The state's governor's declaration is also required for federal assistance, according to the Stafford Act.

Although the federal government provides substantial resources, local agencies still carry the greatest responsibility for disaster management. Disaster preparation and response is widely viewed as the appropriate role of government, and most citizens expect government, especially their local government, to take an active role. At the local level, the department of emergency management plays a key role in disaster management as the main coordinator of all agencies. Sometimes a task force may be set up with officials from local emergency management departments,

成都消防05
东山
东救援

An elderly woman is rescued on May 14, 2008, after being trapped for more than 50 hours in the destruction caused by the 2008 earthquake in Dujiangyan City, Sichuan Province, China. Collaboration was at work in this crisis: Nongovernmental organizations provided assistance to victims and raised $6 billion in aid. Private companies provided free temporary housing, permanent home construction, and cell phones to survivors. Finally, over 75 percent of victims were rescued by mutual aid from local citizens.

related governmental agencies such as the department of health, department of civil affairs, and fire and police departments, as well as representatives of the private and nonprofit sectors. These agencies take on specific tasks in the event of a disaster, from placing road closure signs to providing food, building shelters, and the like.

The 2009 Georgia flood demonstrates a successful intergovernmental collaboration. In September 2009, Georgia experienced historic flooding. Following the emergency, the Governor's State of Emergency Declaration was issued, followed by the Presidential Disaster Declaration. Fourteen counties were qualified for federal assistance. During the disaster, local agencies such as the Georgia Emergency Management Agency, Georgia Department of Community Health, and Georgia Department of Community Affairs played a proactive role in the response and recovery process. A Unified Command System was set up to help coordinate interactions among these agencies with "jurisdictional, geographical, or functional responsibilities" toward joint efforts. For example, firefighters in Taylor County assisted local authorities with road damage assessments. They also assisted the Department of Natural Resources in water rescues in Douglas County and other areas. In addition, Georgia received interstate assistance from North Carolina and Alabama, which provided public assistance coordinators. The successful management of the 2009 Georgia flood is to a great extent attributed to effective and efficient intergovernmental collaboration.

Public–Nonprofit Collaboration

For a long time, people considered natural disasters as "God's action," and disaster preparedness and response were mainly the responsibility of individuals and local communities. However, the disruptive and dynamic nature of disasters often exceeded the capacity of the community level. Multiorganizational responses become essential, especially the collaboration between the government and nonprofit sectors. No single department or agency has sufficient resources to deal with the major disaster at hand.

Developing close working relationships and strong collaboration between governmental emergency management departments and nongovernmental organizations (NGOs) leads to more effective and efficient disaster response and recovery activities. NGOs are agile and less bureaucratic than government agencies; however, NGOs' limitations in resources, accountability, and coordination sometimes undermine their effectiveness and efficiency as well as the equitable distribution of services. Also, donors tend to be interested in immediate disaster relief rather than longer-term recovery and mitigation, so the voluntary sector alone is not capable of both coordinating and guaranteeing a just and effective social response to disasters.

Nonprofit organizations and faith-based organizations (FBOs) have a long history in disaster relief work and collaboration with government agencies in the United States. The history can be traced back to 1905, when the American Red Cross declared to receive the Congressional Charter that asked the American Red Cross to carry on "a system of national and international relief in time of peace and apply the same in mitigating the sufferings caused by pestilence, famine, fire, floods, and other great national calamities, and to devise and carry on measures for preventing the same." The congressional charter still operates today.

The Federal Emergency Management Agency (FEMA), as the main governmental disaster response agency, has a long and close relationship with the National Voluntary Organizations Active in Disaster (NVOAD), which is the main national network of NGOs related to disaster activities. In October 1979, soon after FEMA was established, John Macy, the director of FEMA, met with the NVOAD membership. In response to this meeting, NVOAD appointed a committee to work closely with FEMA on an ongoing basis. Now the relationship has grown to the point that FEMA currently participates actively in NVOAD's board meetings, committee meetings, annual meetings, and the annual VOAD leadership conference. At the national level, the NVOAD offers a forum for communication between the many active voluntary agencies on a wide number of issues. At the regional level, FEMA participates in state VOAD activities and encourages close working relationships. Through these methods, FEMA has developed strong rapport with local and state-level VOADs throughout the country.

Also, FEMA continues to maintain its memoranda of understandings with individual voluntary agencies and works closely with NVOAD members individually. FEMA contributes to the public awareness of NVOAD, contributes to the training of NVOAD and VOAD members, assists NVOAD in helping its members contribute to disaster mitigation, and assists NVOAD in the development of a partnership between its members and the business community. And NVOAD agreed to lead and encourage the mitigation of natural hazard risks through outreach, education, and local community involvement both before and after disaster occurs; encourage linkages between governments, the business community, and the state and substate VOADs; assist FEMA when a major disaster or emergency is declared; encourage its members to regularly share information about field disaster response and recovery activities with FEMA regional offices; and disseminate FEMA emergency management information through its membership.

NGOs play a vital role before, during, and after a disaster. NGOs have direct contact with the mass population. Their informing of the public and a close relationship with local communities makes it much easier for NGOs to integrate people into disaster preparedness and training. During and after a disaster, NGOs collaborate with first responders, governments at all levels, and other agencies and organizations providing relief services and fund-raising to sustain life, reduce physical and emotional distress, and promote recovery of disaster victims when assistance is not available from other sources. NGOs have their specific target groups with a focus on a certain social problem, and they clearly understand the needs of disadvantaged groups such as the elderly, children, and the disabled. Also, because NGOs provide professional service in daily life, they are more professional and efficient in providing services for victims. For example, in the 9/11 World Trade Center attack in 2001, volunteer psychological organizations provided psychological counseling for emergency responders and victims afterward. In the 2008 Wenchuan earthquake in China's Sichuan province, Save the Children focused on providing assistance to the child victims. Moreover, NGOs play an important role in collecting funding and resources. NGOs have connections with enterprises and governments nationwide and internationally. They can effectively raise money or resources by organizing donation of money, clothes, or food. In the Wenchuan earthquake, NGOs such as the Red Cross raised about $6 billion, which accounted for 31 percent of total funding. What is more, participation of NGOs in disaster management fosters the consolidation of the society and increases people's sense of responsibility.

Public–Private Collaboration

The private sector also plays a key role in every phase of crisis management. Many private-sector organizations are responsible for operating and maintaining the nation's critical infrastructure. Privately owned critical infrastructure, key resources, and other private-sector entities are significant to local, regional, and national economic recovery from incidents. Examples of privately owned infrastructure include transportation, telecommunications, private utilities, financial institutions, and hospitals. Also, many private sectors have their own continuity plans to deal with disasters, which ensure their continuous operation.

Participation of the private sector during a response varies based on the nature of the organization and the nature of the incident. Generally, there are three types of collaboration of the private sector with the government and nonprofit organizations. First, owners of certain regulated facilities or hazardous operations are usually legally responsible for preparing for and preventing incidents from occurring and responding to an incident once it occurs. For example, federal regulations require owners of nuclear power plants to maintain emergency plans and facilities and to perform assessments, prompt notifications, and training for a response to an incident. In the historical snowstorm in South China, electric power companies were required to clean the ice on the power poles to maintain the electricity provided to local communities.

Second, many private-sector companies voluntarily participate in disaster preparedness, mitigation, and recovery for no profit. This embodies the sense of corporate social responsibility (CSR). Nowadays, as the private sector becomes the main fosterer in economic development, it has much more involvement in social development than ever before. Not only does the private sector provide better technology, products, and service to the society, it also relies more and more on the development of the society that provides it with a safe and stable social environment and consumers with affordability. Also, enterprises with a good image among the mass population tend to attract more consumers. This interdependence motivates many private-sector firms to volunteer for disaster response activities. In the Wenchuan earthquake, many companies volunteered to provide free tents and movable shelters for temporary victim housing. The telecommunication company offered free cell phones to survivors to reach out to their relatives. Construction companies promised to rebuild houses for the victims at no charge.

Finally, other private-sector companies participate in disaster management in the form of a paid contract with the government. The contract requires the companies to promise to provide certain products or services to the community once a disaster strikes. The government pays for their expenses. This encourages enterprises to produce or store products specified by the government that are mostly needed by local communities, not only during and after a disaster, but also before a disaster. For example, local government can sign a contract with companies producing extinguishers, fire hammers, and wires. This contract form provides a more agile and efficient model and largely reduces either shortage or waste of necessary resources.

Collaboration With Citizens

Citizens, whether affiliated with a group or independent, are an indispensable part of disaster management collaboration. They have a strong desire to make efforts to increase their safety and that of their families and communities. The mobilization of organizational and individual volunteers also serves a social-psychological purpose in that it brings communities together and gives them a sense of efficacy.

Citizens are always the first responders at the disaster scene—before other assistance such as the military or medical groups arrive. In the Wenchuan earthquake, 70,000 survivors out of 84,000 trapped in the debris or injured were rescued by mutual aid from citizens. Less than 17 percent of the survivors were rescued by professional groups, who arrived hours or days later.

To promote citizens' role in all phases of emergency management, it is necessary for them to receive training in advance. The residents should be educated in disaster procedures and mitigation endeavors. Through this process, they become more self-reliant and supportive of what emergency services can provide.

Achieving Successful Collaboration

Collaboration of varied governmental agencies can be better reached with preestablished frameworks such as mutual aid agreements and memoranda of understanding to provide or receive assistance in disasters. A good example is the Emergency Management Assistance Compact (EMAC), a state-level mutual aid agreement. According to this agreement, states can share resources in the event of a disaster. States that provide assistance can be reimbursed by FEMA for their expenses. For example, FEMA reimbursed more than $30.4 million to the state of Mississippi for receiving more than 24,000 victims from other states in the event of Hurricane Katrina.

Successful collaboration also requires excellent personal skills in leadership and communication of emergency managers. Matching organizations' skills and abilities to the tasks at hand is no less important than matching employees' skills and abilities to their job descriptions. Successful collaboration depends on a clear understanding of each entity's roles and responsibilities in emergency management. Thus, emergency managers must be familiar with the functions and capabilities of all departments, agencies, and organizations at various levels of government as well as of other entities in the private and nonprofit sectors. Emergency managers not only must be aware of the number and diversity of agencies involved in disasters but also must improve their administrative skills and their ability to improvise in cooperation with others. Different organizations have their unique missions and values, different cultures, and running models. Misunderstanding of a key word in disaster management among organizations could cause big trouble. Also, conflict among agencies could greatly lower the efficiency of disaster response activities. Thus, emergency managers need to sharpen their skills in leadership and communication to reach a better collaboration in crisis management.

Command and Control

In the context of emergencies, “coordination” means conducting processes and operations so that their functionality is guaranteed, usually by ensuring that people and organizations work together to good effect. The term *command* means giving formal orders and instructions to people and groups so that they will take particular actions. Principles of command and control in civilian emergency management are derived from military practice and reflect the need to ensure that response operations are orderly and disciplined. Systems need to be designed to ensure that the commanders do not lose sight of the “big picture” (i.e., the context of emergency operations). This is achieved by ensuring that command decisions are based on sound procedures, experience, and information relayed from the field of operations.

Emergencies tend to be chaotic situations characterized by the imperative need to limit casualties, destruction, and damage. Data on the evolving crisis may be insufficient, uncertain, and ambiguous, and there may be sudden, unexpected developments to which the response mechanisms must adapt with great rapidity. In crisis situations, emergency managers will probably suffer from stress and tiredness, but they must maintain clear objectives, interact effectively with many people, and communicate lucidly. Emergency response organizations may have shifting, competing goals, yet in managing them, emergency commanders need to be aware of the terrible potential consequences of errors, inefficiency, negligence, or inactivity.

This article considers the nature of emergency command (including changing trends in the modern era). It reviews two models of emergency command (incident command system and the gold-silver-bronze model) and will conclude with some remarks on contemporary challenges in command and control.

Anatomy of Emergency Command

There are two basic models of emergency management that constitute the end members of a spectrum, along which many different permutations are possible. The "command function model" groups the emergency functions around a locus of control, the chain of command, which comprises a hierarchy of tiers determined by decision-making competencies at each level. Typically, the levels are strategic, tactical, and operational. The "support function model" is nonhierarchical and relies more on collaboration than on command. Relationships between emergency managers are based more on specific functional sectors than on position in a hierarchy of decision makers. Examples of the sectors include search and rescue, materials and supplies, logistics, transportation, communications, and shelter. The command function model assumes that the responses of the many organizations that participate in emergency operations need to be centralized and formally directed by a hierarchy of authoritative people. The support function model assumes that a crisis can be managed by allotting competencies to task forces and ensuring that they exchange information adequately and address all needs generated by the emergency. As these are end members of a spectrum, most forms of crisis management that are actually used are less extreme than a purely command-based or purely collaborative approach and thus represent a compromise between models.

In the modern world, emergency conditions favor uncertainty, diversity, informality, and decentralization. Therefore, emergency management means coordinating more than controlling. Moreover, in general terms, everyone wants to command and control, but not everyone is happy to be commanded and controlled. This is evident at the grass-roots level of relief efforts, where decision-making processes tend to be pluralistic and decentralized. At the same time, information and communications technologies have become an important and accepted part of crisis response, and their effect has been to reduce the need for centralized or hierarchical decision making and promote a more collaborative approach. In brief, they have flattened the chain of command.

The modern emergency manager is more a controller of resources than of people. Besides personnel, the resources consist of light and heavy vehicles (possibly including aircraft), specialized equipment, materials and supplies, buildings and structures, and the means of rapid communication. Stated in other terms, the "raw material" of emergency command is made up of structures, things, and tasks.

The choice of management model depends on the forms of public administration that prevail in a particular country, and also on cultural factors. Where autonomy and individualism prevail, a more collaborative model is required; where people are accustomed to waiting for orders, a more command-based model is appropriate. In either case, there will be a "lead agency," either by default or by design. This is the reference organization for basic command in the incident. It will be charged with assuming a coordinating role and presiding over decision processes, above all at the site of emergency operations. The lead agency could be any of the main emergency response organizations, and which of them is chosen depends on both the national culture of emergency response and the problems encountered in typical national emergencies. In Italy, the Fire and Rescue Service is the lead agency, as in major disasters such as earthquakes, firefighters have the lead role in search and rescue and making environments safe for other responders to enter. In Britain, the lead agency is usually the police, because emergencies are seen first and foremost in terms of the need to maintain public order.

Arrangements exist to let the other services take over the lead role in specific kinds of emergency. In the Islamic Republic of Iran, the Red Crescent is usually the lead agency, as earthquake disasters are usually major mass casualty events.

A common emergency management system is the incident command system (ICS), in which the lead agency role is in many cases occupied by a fire service.

Incident Command System

The incident command system (ICS) began with a radical reorganization of wildfire-fighting activities in California after a particularly difficult day in August 1970 when centralized command was unable to cope with almost 200 simultaneous environmental fires. The ICS is a modular system with command instituted at the site of the incident. Emergency operations grow with continuing assessments of needs and the arrival of new resources at the site. The ICS offers a means of coordinating the work of organizations and task forces and ensuring that they strive toward common objectives, such as stabilization of the incident and protection of lives, property, and environments.

At each site there is an incident commander, who provides local leadership and should be the most appropriate person to do so, on the basis of rank, experience, and training. He or she coordinates operations at the scene. A planning officer acts as the point of contact between the incident commander and the organizations that respond to the emergency. He or she collects and evaluates information on the incident, helps the incident commander to define operational priorities, and disseminates information on the progress of the incident and the corresponding operational response plan. The plan is put into action by the ICS operations section. At the same time, the logistics section acquires and manages the materials, equipment, and services required to support the emergency responders. The logistics team follows the instructions of the incident commander and the operations section. At the flank of these workers, a safety officer monitors risks associated with operations at the site and ensures that all emergency responders are properly protected. An information officer liaises with any mass media representatives who are present and ensures that the incident commander can communicate efficiently with the emergency operations center that provides support and backup to the field team. Finally, the accountability and administration section monitors and registers expenditures and manages administrative processes. A simplified diagram of the ICS is shown in Figure 1.

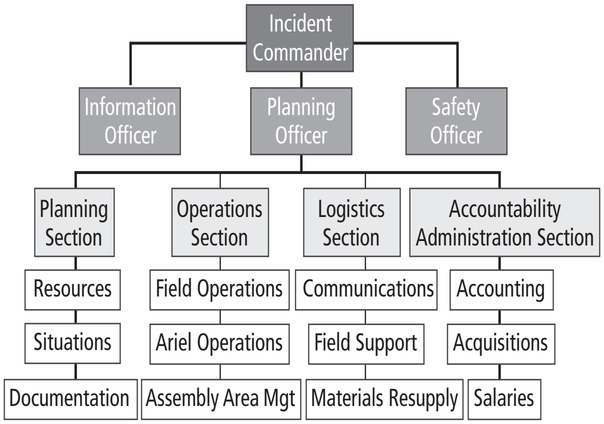

Figure 1 Simplified diagram of an incident command system

In this way, the ICS is designed to ensure that command processes are logical, acceptable, and transparent; that responsibilities for action are fully assigned; and that emergency responders are able to divide up tasks, collaborate, and provide each other with any mutual assistance that may be required. Flexibility is ensured by the fact that on-site command and competencies can be passed instantaneously from one person to another by the mere act of taking off or donning a reflective tabard, and also that the system embodies the delegation of responsibility to individuals, teams, and task forces. Compared with many other forms of command, the ICS has improved information sharing, collaboration, communication, efficient use of resources, and safety and security of responders. It has reduced the span of control and favored realistic forms of management, especially across different organizations (in very large disasters, more than 100 of these may be present in the field).

The ICS is satisfactory when its objectives are clearly defined, reasonable, consistent, and adequately prioritized. Critics of the ICS have argued that it does not function well in large disasters (i.e., that it is inherently suited to small, self-contained emergencies, such as localized transportation crashes or house fires). It is difficult for the system to absorb groups of responders who are independent or poorly organized—the so-called freelancing problem. Critics say that it can cause a large convergence reaction of emergency personnel, equipment, and resources, but it remains too simplistic to manage these, especially over long periods of time. Indeed, it has been argued that the ICS can create inflexibility when conditions change rapidly and unexpectedly. Moreover, the emphasis on "command" could signify authoritarianism. In synthesis, the ICS seems to be least effective when there are rapid, multiple impacts in a limited geographical area, where many organizations seek to achieve many different goals, and where the varied objectives of emergency operations conflict with one another.

The protagonists of the ICS respond that many of its inefficiencies result from failure to train and exercise participants in using the system, or from its application in contexts for which it was not designed. The best conditions for the use of the ICS are those in which there is no lack of trust or leadership, participants know each other and work well together, the tactical plan of action is established before the incident, all participants are well aware of the nature and magnitude of the incident, and there is a good consensus among all the emergency responders. However, one could argue that these are preconditions for good emergency response whatever the command system employed.

Despite reservations about the validity of the ICS, it has been widely adopted since it was devised more than 40 years ago. The U.S. National Incident Management System (NIMS) is a form of ICS designed to be used in national emergencies and embodies a full-scale multiagency coordination system. In the United Kingdom, the Medical Incident Management System (MIMS) is a variant of the ICS designed to codify on-site responses to medical emergencies by health personnel. Outside the United States, applications of the ICS are more commonly limited to particular services than applied to the whole spectrum of emergency response organizations. In Italy, for example, the National Fire and Rescue Service has its own ICS, but this does not extend to the organizations with which it works (police, medical first responders, volunteer groups, etc.).

The British Command and Control System

The national emergency management system in the United Kingdom is hierarchical and based on a tripartite distinction between "bronze" (operational), "silver" (tactical), and "gold" (strategic) levels. In addition, "platinum" (or "diamond") is the policy-setting level, but it is not intended to be activated during emergencies. Instead, the highest level of emergency command is represented by the Cabinet Office Briefing Room (COBRA) in London, which is a sort of higher-level strategic operations center staffed by senior members of the national government.

In an emergency, the bronze level (operations) is activated before the silver and gold levels. The bronze commander must first estimate the geographical size and seriousness of the problem. He or she assigns control of a specific geographical area to a particular commander and begins the process of coordinating organizations that work at the site. Multiple sites thus require multiple bronze command posts and commanders. Silver (tactical) command may be based in an urban center near the incident, in many cases in a local police station. Silver determines priorities in the allocation of resources, plans and coordinates tasks to be carried out at the site or sites, establishes general command over all operations, and maintains a register of decisions and actions taken. The silver commander decides whether to activate the emergency plan and puts into action the measures needed to tackle the incident. At one further remove, gold (strategic) command locates and supplies adequate resource support to tactical commands and forms a group to ensure that multiagency response is adequately coordinated. The flow chart of the system is shown in Figure 2.

It is evident that in this system, "gold" must find resources, "silver" must allocate them, and "bronze" must use them. Functional sectors are distributed among the levels of this hierarchy, with the majority of them pertaining to the strategic level. Indeed, the decision may be taken to institute a parallel "gold media command" so that intensive inquiries by mass media representatives can be answered without interrupting the emergency response chain of command.

Are Command and Control Really Necessary?

It is evident from the description of these two systems that the ICS uses a more collaborative approach and the UK system is oriented more toward a traditional model of military origin. Command and control appear in various forms in both systems, but are they necessary at all? It could be argued that command merely takes away a sense of individual responsibility from whoever is commanded, and that it inhibits creativity and flexibility in the face of complex, intractable, and rapidly mutating problems.

There is no doubt that adaptive management is needed in the modern emergency. Responding adequately is no longer a process of applying the rules and waiting for the results. One must be able rapidly to recognize the magnitude of the event: A state of emergency must be declared at a very early stage in a synchronized way between participating organizations; this will enable them to move from normal operations to emergency response mode in which nonessential tasks are dropped. Above all, there must be good lines of communication between organizations and full sharing of information.

A good leader is a person who has clearly defined responsibilities and is fully aware of them. He or she has previous experience managing emergencies and is well able to carry out the appropriate tasks associated with managing the emergency. He or she is able to balance detachment with involvement, to avoid the decision-making rigidity that goes with tiredness and stress, and to stop burnout from occurring. From the point of view of team members, the leader should satisfy the dual need for a way-finder and a protector. The extent

Commodity Shortages

The most practical definition of a "commodity shortage" is the inability to obtain key items such as articles that can be used for trade. These may include gold, silver, spices, apples, grain, or related items. A commodity shortage may lead to a large crisis secondary to the lack of important supplies such as food or medical supplies. Moreover, communities often face illness due to a lack of simple commodities such as cleaning supplies, soap, or shoes. It is important to note that services are not typically defined as commodities.

Reasons

Commodity shortages are quite common during a crisis. There are several reasons for shortages, including a decrease in production resulting from a lack of materials or manpower, pestilence in the food supply, a lack of transportation assets or routes, or a divergence of supplies to a crisis area. Divergence of supplies to areas stricken by a crisis or affected by military action often reduces the amount of commodities available for the public. Since commodities may be very limited in many areas, this divergence will severely impact the civilian population. Storage concerns are also a major concern. Many nongovernmental organizations (NGOs) provide commodities, especially food, during crises. However, government programs also provide food supplies and other commodities in partnership with NGOs. The military often works with these organizations to ensure that emergency transportation assets are available whenever private resources may not be readily available.

A decrease in production secondary to a lack of raw materials or manpower often occurs during extraordinary events. The most common reasons for a lack of raw materials include reduced production, shuttering production facilities due to crisis, overusing raw materials, or reduced ability to obtain raw materials to produce commodities. Since finished products such as generators, vehicles, or toilet paper cannot be produced without parts or raw materials, production facilities have no choice but to cease production whenever they are unable to obtain raw materials.

Some raw materials such as platinum are so hard to obtain that the world supply is often reduced in an effort to prevent large shortages of the commodity. Other commodities such as medications used to fight cancer or control diabetes are in short supply because production facilities have lost patents, thereby reducing profit margins. These facilities often choose to cease production rather than lose profits. This leaves suppliers trying to find other ways to obtain commodities, which may not be possible. Moreover, the price of the remaining commodities is often so high that only the wealthy can afford to purchase them. The availability of certain commodities may also be secondary to geographical location of those seeking the commodity. For instance, it may be quite easy to obtain a petroleum product, such as diesel, in areas near refineries or where pipelines are readily available, but it may be hard to obtain in areas that require extended shipping methods. Commodity shortages are also common during work stoppages.

Pestilence in the food supply may reduce the availability of fruits, vegetables, and grains. Although chemicals are often used to reduce attacks by these pests, it is quite common for many areas of the world to experience infestations. Farmers in underdeveloped countries do not have access to a ready supply of pesticides or the equipment to deliver them; therefore, these areas of the world are accustomed to infestations. However, many developed countries also experience their own infestations. For instance, both China and Russia have experienced attacks by large swarms of locusts, thereby reducing their food supply. Countries then have to allocate funds to purchase food supplies from countries such as the United States or Brazil.

A lack of transportation assets, such as trucks or ships, may create a commodity shortage. This may be due to poor road conditions, work stoppages, lack of spare parts for repairs, or a lack of trained operators or pilots. Additionally, during a crisis these transportation assets may not be available because they are diverted for use in more critical areas.

Severe weather also limits the number of transportation assets that may be available. For instance, during an ice storm it is not always possible for large trucks to move along roadways because they are impassable. Severe weather also impacts other transportation assets such as aircraft and shipping, both of which may not be available during extraordinary times. Aircraft may not be able to access a given area due to weather conditions or because the weather may have deteriorated runways. Operators and pilots may also refuse to enter crisis-stricken areas, such as those experiencing armed conflict, thereby creating a lack of transportation assets in a given area. Obviously, if an area experiences a lack of transportation assets, then it is likely that the area will not receive needed supplies. This reduces food supplies, medical supplies, and equipment, thereby creating a commodity shortage. It is important for private and public entities to plan ahead by delivering needed commodities ahead of time. Many communities and organizations periodically order important commodities in order to prevent shortages due to transportation concerns. Moreover, these organizations may order extra supplies so that they can use them should a commodity shortage occur due to transportation concerns.

Organizations often experience a commodity shortage simply because they do not have adequate storage facilities. If commodities are not properly stored, they may be lost due to a variety of reasons, including theft, damage, pestilence, or other infestations. Many communities lack adequate storage facilities for both perishable and nonperishable commodities for a variety of reasons. These reasons may include lack of funding to purchase proper storage facilities, lack of security forces, and lack of experience with commodity storage, especially for foodstuffs and medical supplies. It is not uncommon for organizations in crisis-stricken areas to lose the majority of their commodities due to theft. These organizations are often prohibited from employing armed security forces, so they understand that theft by armed groups is to be expected with commodities.

In war-torn areas of the world, it is quite common for the general population to experience a commodity shortage. As many of these areas are ruled by dictatorships, the government simply ensures that its own forces are supplied with the majority of goods while the population receives very little. Unfortunately, during a commodity shortage the available supply often goes to the highest bidder instead of to the people who need the commodities most. Because the poor do not have the resources to purchase these high-priced commodities, they face injury and death. Governments and NGOs often deploy troops or large groups of volunteers to counter these efforts by rough leaders. The United Nations may intercede by providing transportation assets and manpower to deliver and protect key commodities such as food, water, and medical supplies.

Organizations such as the World Health Organization (WHO), Doctors Without Borders, and Feed the Children are often called upon to supply key commodities such as food, medical supplies, and water to areas of the world experiencing a shortage. These organizations often work in conjunction with or under the direction of the United Nations (UN). The United States government is the largest supplier of emergency commodity supplies of any nation in the world. Food supplies, clothing, and other items are often sent to areas facing crisis through the United States Agency for International Development (USAID), an agency of the U.S. Department of State.

Prevention Efforts

Commodity shortages may be reduced by effectively planning for crisis in advance. These efforts include stockpiling food supplies and protecting food supplies from viruses, bacteria, and pestilence. Medical supplies and equipment can also be stockpiled in strategic locations to prevent shortages. Stockpiling these supplies and equipment in secure locations to protect them from the weather, theft, or pestilence is the key to reducing future shortages. Nongovernmental organizations and government agencies alike often pre-stage commodities should they be needed during a crisis. These commodities include medical supplies, foodstuffs, parts, shoes, bedding, clothing, and related equipment and supplies. Governments can also prevent commodity shortages by working with the private sector to ensure that commodities remain available as needed. Developed countries can also work together to prevent armed conflicts or provide specialized military teams whenever armed conflict is all but unavoidable.

Contingency Planning

Contingency planning in emergency management takes place within many different contexts and management settings. This has led to variety in management approaches and the terms used to describe contingency planning. To provide a broadly applicable definition of contingency planning in emergency management and draw attention to some examples of approaches and terms applied in different settings, seven areas of contingency planning will be reviewed: the definition of contingency planning, the importance of contingency planning, the governance context of contingency planning, contingency planning and international assistance, contingency planning in national settings (the United Kingdom and the United States), multilevel coordination, and contingency planning and complex systems.

Defining Contingency Planning

The *Oxford* dictionary defines the word *contingency* as "a future event or circumstance which is possible but cannot be predicted with certainty." Contingencies (such as a tsunami, earthquake, drought, or epidemic) that produce emergencies are the focus of contingency planning. The Inter-Agency Standing Committee (IASC; a forum involving United Nations and non-UN partners for humanitarian assistance) defines contingency planning relating to humanitarian crises, but the definition is applicable more generally and is a recognized standard within the United Nations system. The IASC defines contingency planning as "a management tool used to analyze the impact of potential crises and ensure that adequate and appropriate arrangements are made in advance to respond in a timely, effective, and appropriate way to the needs of the affected population(s). Contingency planning is a tool to anticipate and solve problems that typically arise during humanitarian response."

In research on drought contingency planning for the United Nations International Strategy for Disaster Reduction (UNISDR), Lesukat Marko points out that emergency managers sometimes use the terms *contingency planning* and *contingency plan* interchangeably. He draws attention to the important conceptual distinction between these terms, showing that while contingency planning is a systematic management process, a contingency plan is a product of that process.

Importance of Contingency Planning

When carried out well as part of an integrated approach to emergency planning, contingency planning enables planners to anticipate problems and identify appropriate responses to deal with emergencies. Contingency planning ensures that public agencies, nongovernmental organizations (NGOs), and communities are better prepared for situations that require emergency response. Contingency plans detail specific risks that require attention beyond the provisions of general plans. Contingency plans contribute to an integrated approach to emergency response and highlight specific training and exercise requirements to deal with particular kinds of emergency. Good contingency planning thereby enhances organizational and community resilience.

Governance Context

Different management regimes provide different national and agency contexts. United Nations agencies and national governments that commit to democratic, effective, and efficient emergency management recognize the need for a governance framework that provides the conditions for effective leadership to guide the planning process; accountability and transparency in management; the participation of stakeholders in the planning process; good coordination and communications; and the enhancement of sustainability, robustness, and resilience.

International Assistance

The UNISDR promotes common understanding and usage of disaster reduction concepts, and the Hyogo Framework for Action (HFA) 2005–2015 underlines the need for more consistent terminology related to disaster risk reduction. The IASC regards contingency planning as part of preparedness in accordance with Priority 5 of the HFA that refers to "strengthening disaster preparedness for effective response at all levels." Preparedness under the HFA involves "increasing the capacity to predict, monitor and be prepared to reduce damage or address potential threats" and "strengthening preparedness to respond in an emergency and to assist those who have been adversely affected."

This requires that stakeholders work together effectively. According to UNISDR, contingency planning "results in organized and coordinated courses of action with clearly-identified institutional roles and resources, information processes, and operational arrangements for specific actors at times of need." Contingency planning, for UNISDR, allows "key actors to envision, anticipate and solve problems that can arise during crises." Contingency planning is an important aspect of overall preparedness, and it is a process involving the regular updating and exercising of contingency plans. The UNISDR regards the strengthening of national integrated mechanisms conducive to effective preparedness planning.

Jim Good, writing for the United Nations High Commissioner for Refugees (UNHCR), describes this as a "dynamic process" where it is important to move beyond the limitations of formalistic contingency plans that may not properly fit into a wider strategic framework of emergency planning. As Lesukat Marko shows, contingency plans on their own are insufficient to achieve effective preparedness and response. Contingency planning should be part of a wider integrated strategy where the linkages between preparedness, response, and recovery are explicit, with a commitment to community resilience and sustainability. The International Risk Governance Council (IRGC) points out that contingency planning should nest within a broad risk governance framework where stakeholders should be alert to complex and emerging risks as well as to the specific risks alluded to in contingency plans. Risk and emergency management will significantly contribute to resilience if stakeholders appreciate the complexity and interdependencies of systems that can produce unexpected types of emergency and multi-hazard disasters.

In its report titled "Inter-Agency Contingency Planning Guidelines for Humanitarian Assistance," the IASC refers to international assistance efforts involving UN agencies, NGOs, and others such as the International Red Cross. The IASC advocates general preparedness planning that establishes a standing capacity to respond to emergencies together with contingency planning that is preparedness and response planning for a specific emerging or anticipated crisis. General preparedness planning and contingency planning share many of the same planning activities, the main difference being the concentration in contingency planning on a specific risk or risks.

Contingency planners therefore need expertise in response preparedness, needs assessment, and coordination while they assume responsibility for addressing a specific risk or risks. Contingency planners must understand the nature of coordination between agencies and other stakeholders and should address coordination gaps. Contingency planners must be aware of the capacities, including training and skills, of potential responders, and contingency planning generally involves putting in place a trigger or link to an early warning system that puts the contingency plan into operation.

According to the IASC guidelines, there are four elements demanding strong coordination and process management in their conception of the contingency planning process. These elements are the following:

- *Preparation:* Preparing for and organizing the contingency planning process.
- *Analysis:* The assessment of hazards and risks, building scenarios, and developing planning assumptions.
- *Response planning:* Defining response objectives, defining coordination and management arrangements, and developing and embedding response plans.
- *Implementing preparedness:* Regarding the planning process as iterative, leading to continual improvement.

For the IASC, the contingency planning process generates outputs reflecting the different phases of planning, and these outputs, according to the IASC guidelines, should be included in a contingency plan typically constructed as follows:

- *Executive summary:* An overview of the plan and its elements.
- *Hazard and risk analysis:* A brief summary of the hazards and risks analyzed as part of the contingency planning process.
- *Scenarios and planning assumptions*: Brief summaries of agreed scenarios and planning assumptions underlying the contingency plan.
- *Objectives and summaries:* Concise statements of objectives, strategies, and guiding principles.
- *Overall management and coordination arrangements:* Identifying clusters and designated lead agencies/organizations (with a diagram showing coordination mechanisms), and covering arrangements for appeals and funding, information management, and cross-cutting issues.

- *Summary of sector/cluster response plans:* (a cluster is "essentially a sectoral group," such as education or health): Outlining sectoral participation, objectives, and response actions along with a gap analysis and indication of the standards guiding response.
- *Preparedness actions:* Agreed priority preparedness actions, and preparedness actions by sector.
- *Annexes:* Summaries of sector plans, a schedule for the implementation of preparedness actions, and terms of reference for sector/cluster groups.

The IASC emphasizes that contingency plans are not instruction manuals for responders. Instead, they establish working relationships, standards, and coordination between stakeholders. Contingency plans thus concern "solving potential problems ahead of time."

Contingency Planning in National Settings

In the United Kingdom (UK), duties under the UK 2004 Civil Contingencies Act oblige stakeholders variously to engage in emergency planning, risk assessment, business continuity planning, warning and informing, and promoting business continuity management. The act mainly concerns preparedness through assessment and preparation. It does not cover response and recovery directly but does deal with "preparedness for response." Contingency planning, as a pre-emergency process, is an aspect of preparedness for response.

The Cabinet Office guidance on emergency preparedness provides an overview of the emergency planning process that addresses emergencies with domestic and international implications. The guidance establishes principles that apply across a range of emergency planning situations. The guidance commits to Integrated Emergency Management (IEM) that includes six related activities as follows:

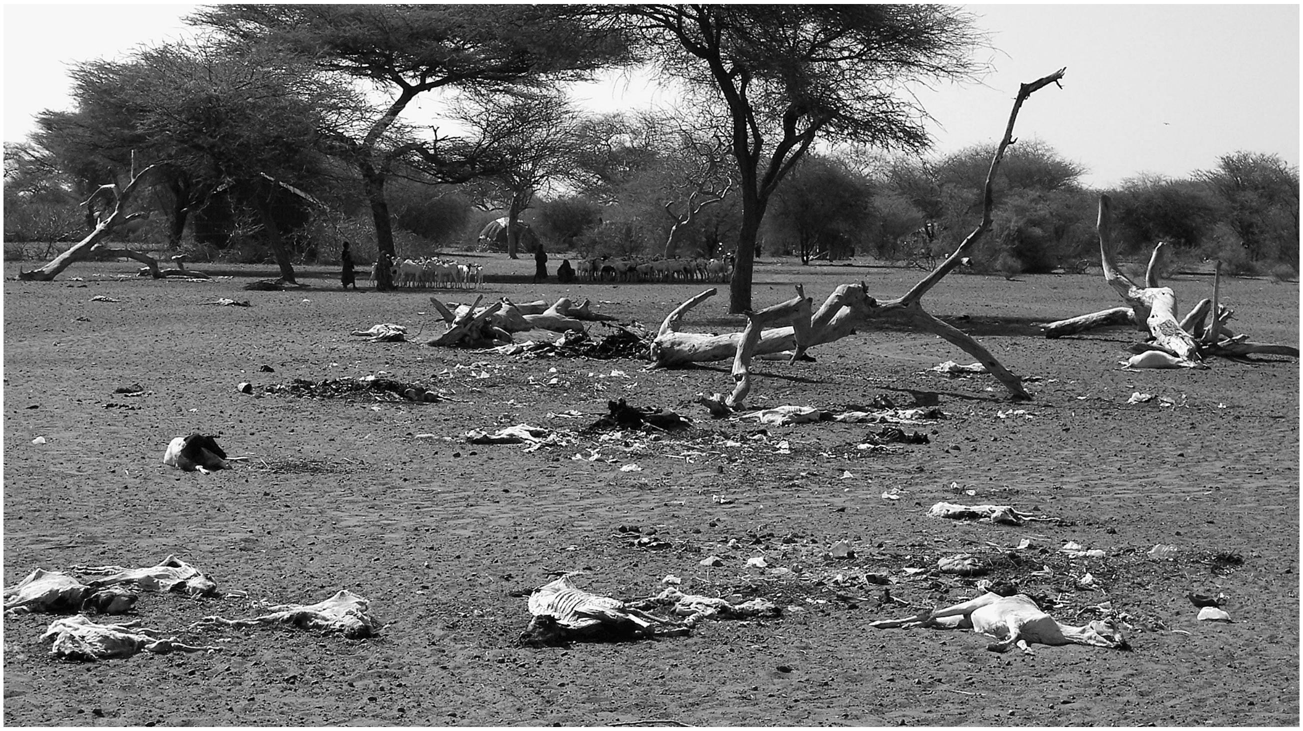
- Four preparedness activities:
    - » Anticipation, or horizon scanning, where responders become aware of risks
    - » Assessment includes risk assessment, capability analysis, readiness assessment, and establishing planning parameters
    - » Prevention deals with fire safety, building regulations, and actions that help prevent an emergency
    - » Preparation includes the production of plans and exercising. It concerns emergency "preparedness for response" set within IEM
- Two post-emergency activities:
    - » Response concerns the detailed decisions and actions to deal with the immediate after-effects of an emergency, such as command and control, coordination, and communications
    - » Recovery concerns the restoration of communities following an emergency

While contingency planning involves "preparation," it is an important element in overall preparedness and IEM. Contingency planning thus involves activities used in other types of emergency planning. For example, it involves anticipating risk and taking account of safety assessments and regulations. Contingency plans refer to these as well as defining response and recovery roles. Because contingency planning concerns specified risks, it involves the development of scenarios for those risks and making agencies and the public more aware of them.

The UK guidance indicates the following plans used in emergency preparedness:

Generic plans relate to any emergency. A generic plan can act as a "core plan" for emergency staff and resource mobilization. Such plans build awareness and complement multiagency integrated major incident response systems such as command and control.

Specific hazard or contingency plans deal with a specific risk or risks, or particular kind of emergency. Contingency plans move from the general to the particular, addressing such events as oil pollution, chemical spill, or flu pandemic. Specific plans generally are multiagency, covering different agency roles. Such plans commonly involve different levels of government, as in the British National Contingency Plan for Maritime Pollution. Specific



The 2005–06 drought in Somalia had a severe impact on livestock. Despite the cyclical pattern of droughts in the Horn of Africa, there are no national preparedness plans in Somalia or Ethiopia. According to a report by the Humanitarian Policy Group, there is an absence of national and sufficient local contingency funds to rapidly implement large-scale plans. The lack of effective coordination between district and national levels prevented existing contingency plans from forming wider national and international responses.

plans are appropriate when generic arrangements are insufficient for dealing with the peculiarities of a particular case. There are specific site or location plans as well as wide-area plans for such events as floods, storms, and chemical contaminations. "Slow-building wide area emergencies," such as severe weather conditions or drought, also have plans. Most responders employ specific plans within the context of a generic plan.

Staffordshire Emergency Flood Plan (SEFP) outlines the contingency planning process with reference to a local flood plan in the English county of Staffordshire, according to Andrew Marshall, director of civil contingencies in Staffordshire. Flooding is one of the greatest risks in Staffordshire, potentially affecting communities, local governments, health sector organizations, the emergency services (fire, police, and ambulance services), and other organizations. SEFP involved more than 40 organizations, over two years, contributing to production of the original 2009 plan. This involved a structured project management approach, including consultation with partners working within the IEM framework.

The Staffordshire Resilience Forum (SRF) is the multiagency partnership responsible for flood contingency planning in the county. The SRF worked with the supporting Staffordshire Civil Contingencies Unit (SCCU) that populated a regularly reviewed Community Risk Register (published on the Staffordshire Prepared Web site). Partners highlighted various risks, thereby helping the SRF to prioritize resources for concerns of greatest need. Flooding ranked as one of those priority needs.

The Community Risk Register led to a formal request for the development of a multiagency contingency/response plan to address flooding through two key meetings. One involved tactical leaders, and the other strategic SRF leaders. Following acceptance of the flooding risk, planners produced a business case behind the requirement for a specific contingency/response plan for flooding. The strategic leaders then agreed on a project to see the planning through, and a local government authority in London peer-reviewed the plan, followed by a three-day multiagency validation exercise.

The United States provides another example involving complex multiagency contingency planning. In the wake of the 2001 9/11 attacks, the United States, Federal Emergency Management Agency (FEMA), along with other federal agencies, programs, and offices, in 2003 became the U.S. Department of Homeland Security (DHS). In 2005, Hurricane Katrina underlined the need for stakeholders to collaborate effectively and rationalize emergency planning. Before Katrina, the DHS produced the 2004 National Response Plan, superseded by the 2008 National Response Framework (NRF), which underscored the need for multilevel coordination.

The DHS Contingency Planning and Incident Management Division (CPIMD) coordinates and implements the "incident management" functions for its Office of Infrastructure Protection (IP) covering contingency planning, preparedness, continuity, and incident planning. Contingency planners within IP work with FEMA officials and others in supporting actions in line with national NRF policy. The DHS supports the development of plans and procedures for preparedness and incident management, and CPIMD has a Business Continuity and Emergency Preparedness Team that ensures that IP operations are effective. National Planning Scenarios depict various "high-consequence" threat scenarios, including terrorist attacks and natural disasters, intended to provide a focus for contingency planning and preparedness work.

The DHS National Preparedness System (NPS) covers preparedness, protection, response, and recovery. A National Incident Management System (NIMS) involves all levels of government, NGOs, and the private sector, providing a standardized framework compliant with the NRF. The NIMS has a clear management process focus, under NIMS strategic, operational, and tactical plans, each incorporating a clearly defined process for joint action and multilevel cooperation through integrated planning. General plans might relate to "scenario-specific" plans or include annexes based on risk assessments, while contingency plans focus on specific risks.

An Integrated Planning System (IPS) (complementing NIMS) applies to federal agencies relying on or helping other agencies, and its plans are in relation to the National Planning Scenarios. The IPS refers to contingency (pre-incident) planning supporting post-incident crisis action planning. As in other nations, the DHS regards contingency plans as concentrating on specific threats or scenarios, and according to the guidance on the Integrated Planning System, contingency planning facilitates a transition to crisis action planning.

Multilevel Coordination

It is thus vital to process-manage contingency planning and coordinate stakeholders, whatever the context. The Staffordshire Emergency Flood Plan depends upon interagency collaboration and coordination in national/local settings. The DHS in the United States refers to coordinating homeland security at strategic, operational, and tactical planning levels, while the IASC refers to three levels of contingency planning in international assistance initiatives involving UN agencies and other stakeholders. The first IASC level involves providing a common framework within which a contingency plan will fit. The second level is sector/cluster level planning, which defines how agencies will work together to achieve sector-specific objectives. At the third level, organization-specific planning defines organizational arrangements. Effective contingency planning involves the interaction of all these levels.

Illustrating this, the International Federation of Red Cross and Red Crescent Societies (IFRC) employs contingency planning as part of a disaster response planning process, with "integrated programming" coordinating stakeholders from different sectors. The IFRC emphasizes risk reduction and mitigation through a form of preparedness planning directly engaging local people in devising and implementing measures to enhance community resilience. However, different stakeholders have different needs, and this makes coordination difficult. Planners need to be sensitive to expectations at each level of planning. At the highest level, "institutional disaster planning" defines the scope of humanitarian action, providing a strategic policy commitment; at the second level, "disaster response planning" involves collaboration to reach a "level of preparedness for timely and effective response." For the IFRC, this involves developing a disaster response plan that is "preliminary in nature" based on "educated assumptions of risks and hazards." At the third level, contingency planning establishes operational procedures for direct humanitarian action. Contingency planning involves "scaling up" to address specific risks likely to have been identified during general response planning. The contingency plan can address local, national, regional, and international risks, as with earthquakes, terrorist attacks, and epidemics. The contingency plan defines operational procedures for responding to a disaster based on anticipated levels of resources and takes account of the available resources and capacities of organizations and communities.

Contingency Planning and Complex Systems

Much thinking underlying contingency planning reflects rational management attempts to identify and concentrate upon specific risks. In the past, emergency planners have often tended to be "plan focused" and less concerned with processes and complex interrelationships between different kinds of risk. According to the IRGC, such "reductionism" tended to focus down on particular problems and modes of preparation at the expense of holistic thinking about the complexity of crises. The IRGC regards contingency planning as a valuable management tool, but for the IRGC it is important continually to learn lessons from emergencies by holistically viewing systems complexity and appreciating "emerging risks" that are familiar or new risks, which become apparent in unfamiliar conditions.

Contingent Coordination

Coordination within an organization is often viewed as a critical factor in success. Effective coordination ensures that all organizational activities are working in an aligned manner, recognizing that the functional areas within any organization are often interdependent. The concept is relatively clear for existing organizations, but is less so for the ad hoc organizational structures normally found in crisis management, where multiple agencies may be called upon to work together to address a complex problem.

Traditional Coordination

Traditionally, coordination has been viewed as a managerial role within an organization. Formal leaders are tasked with setting goals for the organization, then ensuring all internal activities are aligned to maximize the potential for efficacy and efficiency. In such instances, coordination is necessary to ensure that all interdependent functions within the organization work in harmony, supportive of the efforts of the collective, with no function being left unaddressed. Within this traditional context, coordination is associated with a number of leadership and management concepts such as the setting of goals, the development of objectives, the allocation of resources, and the establishment of acceptable outcomes.

In a traditional organizational setting, coordination is normally associated with management of that organization. Although some aspects of the organization may be influenced by external factors, including the guidelines of regulatory agencies and market pressures, final decisions related to operational functions are normally developed internally. Although these efforts may be made using a fully authoritarian model, a model that maximizes employee participation, or any permutation in between, there is typically little concern, if any, for aligning operations with the efforts of other organizations, let alone yielding control of operations over to others.

Contingent Coordination

The term *contingent coordination* may be defined as the ability and willingness of organizations to work outside their normal operational and administrative parameters by partnering with other organizations. This partnership is not necessarily reflected in a full integration of multiple agencies into a virtual organization where decisions are made collectively, but instead is reflected by a number of agencies working together by temporarily yielding their authority to another. In doing so, the agencies essentially subsume their organizational goals to the goals of other organizations, with an understanding that, at some later point, they will become the lead agency, with others supporting them in the attainment of their own organizational goals.

There are a number of challenges to contingent coordination. Appointed officials in public organizations often are constrained by the documents that frame their power and discretion. In some instances, while contingent coordination is not prohibited, it is not recognized as an option within the formal organizational framework, which means utilizing such an approach may differ vastly from the past practices of the organization. In effect, it requires appointed officials to exceed their authority, or at least to temporarily yield it, recognizing that in doing so the organization is deferring achievement of its own mission, which could be construed as negligence. This concern may lead to some hesitancy to engage in such practices, especially if the elected leadership of the locality does not encourage or support innovative and flexible approaches. Therefore, while contingent coordination does provide a potentially valuable means for organizations to work together to solve complex problems, to be effective, the approach must be supported by the elected leadership of the jurisdiction.

Coordination and Crisis Management

Disasters rarely pose a single threat to a community. A natural disaster such as an earthquake requires a number of professional disciplines to work together. The same is true in a human-action event. Additionally, disasters rarely remain contained within the limits of a single jurisdiction. Therefore, it is unlikely that any single organization will have sole responsibility for an incident. In practice, the circumstances are more likely to be that multiple disciplines will have concurrent jurisdiction. Illustrative of this, after a tornado strikes, law enforcement seeks to secure the area and search for victims; the fire service concerns itself with damaged structures, chemical leaks, and fires; emergency medical services treats and transports the injured; public works clears the debris; and private utility companies seek to restore services to the affected areas. Coordination of these activities by a single entity is problematic, given that no single agency has sufficient authority or technical expertise for all necessary functions. One means of addressing this in crisis management is to use contingent coordination.

During the response to Hurricane Katrina, this became a significant issue for federal agencies. Formal role delineation was clear but fragmented. Exacerbating the problem was the lack of resources to conduct operations simultaneously. Based strictly on the National Response Plan and normal practices, federal agencies may very well have elected to work on their own areas of primary responsibilities, creating a fragmented response. Instead, representatives from a number of federal agencies discussed the collective issues faced, identified a list of priorities, then yielded their own authority to other agencies temporarily, carrying out operations in a systematic manner, sharing resources throughout. Although this was by no means a universal or perfect approach, in many instances it facilitated a coordinated response that supported efficient and effective delivery of services. This has not always been the case in times of crisis.

Beginning in late 2001, a series of anthrax attacks occurred in the United States. During one such event, the Federal Bureau of Investigation (FBI) and various public health agencies experienced problems. The FBI, noting that terrorism fell within its purview, insisted it was in charge of all operations, stating that no information about the events should be released because it might negatively impact the criminal investigation. Public health agencies at the state and local levels argued that anthrax posed a significant public health risk, making it their responsibility. According to their operational model, an effective response included an active public education campaign of the potential risks, the signs and symptoms of exposure, and the most appropriate means of treatment. This placed the two disciplines at loggerheads for some time. Although they eventually came to terms, an approach based on contingent coordination may have greatly limited conflict.

In 1992, during the Los Angeles, California, riots, a number of local, state, and federal agencies responded to incidents of rioting, criminal activities such as assault and robbery, and numerous fires. Though this was over a decade before the implementation of the National Incident Management System (NIMS), agencies in Southern California were well versed in the Incident Command System (ICS) used in California since the early 1970s. Because of the extensive geographic area involved, as well as the number of differing agencies that were engaged, coordination using an ICS became problematic. Many agencies set up their own ICSs, focusing narrowly on their own jurisdictions or the issues of primary concern to only their agency. Some state and federal agencies continued to use their normal operational approaches, which involved decision making at the state or federal level, with little interorganizational communication evident. Taken together, these actions contributed to role ambiguity, overlapping responses, service gaps, and

Case Study: Motor Vehicle Collision

Contingent coordination occurs every day, often outside the view of the public. It becomes a useful tool whenever multiple agencies with concurrent jurisdiction must work together to achieve success. Though the specifics of this framework may change due to state law, the conceptual model will be consistent.

In many states, by law, law enforcement has full authority over motor vehicle collisions. In many states, by law, fire departments have full authority over hazardous materials spills, including gasoline and oil spilled during motor vehicle collisions. In many states, by law, emergency medical services (EMS) have full authority over any injuries. A potential conflict occurs when these laws look at such issues in isolation, with no appreciation that they may frequently be combined in a single emergency incident. There is usually nothing in the legal structure of public safety that provides for the primacy of a single agency, and also nothing that gives any single discipline authority over the other disciplines.

To address this potential conflict, on-scene emergency responders engage in contingent coordination. Recognizing they all have independent missions, they agree to work for one another. Typically, patient care will take priority, which will result in EMS providers taking the primary role, with the others assisting as needed. Once the patient care issues are addressed, the chemical and environmental hazards are addressed by the fire department taking the lead, with others assisting it. Finally, law enforcement takes the lead in both the investigation of the incident and the removal of debris from the scene, with other agencies assisting it. Instead of using a unified command system, the agencies rotate command authorities based on an agreed upon set of priorities being matched to the technical proficiencies and authorities of each agency.

the appearance that governmental systems had collapsed. To some extent, these issues could have been addressed through contingent coordination, with agencies temporarily yielding their authority to others, but that is not always possible.

During the 1992 Los Angeles riots, a confounding issue for the application of contingent coordination was the presence of the active-duty military. Although National Guard units operating as state units under Title 32 of the U.S. Code can be assigned to work for local and state agencies, under Title 10, neither they nor the active-duty military can be placed under the operational authority of local or state agencies. By law, they are under the direction of the Department of Defense, which permits them to coordinate their activities with others but does not sanction their ability to yield authority. If the Insurrection Act of 1807 is implemented, an area is effectively under martial law, with local and state agencies working for the military. Although this permits direct coordination by the military, it does not permit contingent coordination, as the Insurrection Act does not provide for local or state agencies to exchange command authority with active-duty military forces. Consequently, in some limited instances, contingent coordination may not be possible, though a Unified Command System may still be possible.

A common thread in disaster research involves problems with coordination. In some instances, coordination was ineffective due to a lack of training. In other instances, coordination was limited by interorganizational conflicts. In other instances, coordination was problematic because with all agencies trying to address their own primary concerns first, resources were lacking to provide services at the desired levels of quality and quantity. During crisis management, contingent coordination offers agency leaders a framework for working together to achieve the individual needs of all organizations in an effective and efficient manner, thereby providing higher levels of customer service to their communities.

Comparisons to Unified Command

One of the components of the National Incident Management System relates to command and control, which includes the Incident Command System (ICS). The ICS is a flexible, scalable framework for coordinating a multi-organizational response. When used as an ICS, there is a single incident commander coordinating activities. This is often found when the scale or severity of the incident is small, with a single hazard that clearly fits within the parameters of a single organization, such as a house fire. When multiple organizations have concurrent jurisdiction, the ICS may become a Unified Command System (UCS). In a UCS, representatives from agencies with statutory authority work in unison to make decisions related to the incident. Although this is similar to contingent coordination, there is a subtle difference. In a UCS, multiple organizations make decisions in a collective manner. Using contingent coordination, an ICS will be used, with the person filling the position of incident commander changing based on the agency having the lead role at any given time.

Continual Improvement

Continual improvement in crisis management is the process by which an organization deals with the need for change. Implementing change is essential for organizations to effectively respond to increasingly diverse types of crises. The means by which continual improvement is implemented vary depending on the organization's purpose, function, and structure. However, there are some commonly accepted methods and approaches to continual improvement in crisis management for most organizations, including but not limited to lessons learned from the experience of an actual crisis, contingency and continuity planning, improving coordination and communication, total crisis management (TCM), and implementing best practices.

Learning From a Crisis to Effect Change

In the wake of a crisis, enlightened organizational decision makers adopt a learning orientation and draw upon prior experience to develop new and more effective routines and behaviors that ultimately change the way the organization operates. The best leaders are purposeful and skillful in finding the learning opportunities inherent in every crisis situation. In times of crisis, communities and constituencies expect their public leaders to minimize the impact of the crisis at hand. Public leaders have a special responsibility to help safeguard society from the adverse consequences of crisis. Experts in crisis management note that leaders who take this responsibility seriously are attentive to all crisis phases: the incubation stage, the onset, and the aftermath. Crisis leadership then involves five critical tasks: sense making, decision making, meaning making, terminating, and learning. Lessons learned from surviving a crisis often open a window of opportunity for reform in the future.

Contingency and Continuity Planning

Contingency and continuity plans are essential components of a sound and comprehensive crisis management plan. Contingency plans should contain information and guidance that will help decision makers to consider not only the short-term consequences but also the long-term effects of every decision. Each critical function and process that is necessary to keep an organization running must have its own contingency plan in the event of failure or cessation. Business continuity plans can help minimize the disruption to an organization that undoubtedly occurs in a crisis.

Advance planning and practice help ensure that an organization is appropriately and adequately prepared for a crisis. Crisis management teams can rehearse a crisis plan by developing scenarios simulating collapse or interruption of operations and by responding as planned. Testing and rehearsing contingency plans heightens awareness of the possibility of an actual crisis and prepares crisis team members to act quickly and effectively. Fine-tuning the crisis plan can be undertaken to increase clarity, speed, efficiency, accuracy, and effectiveness of response from the onset of a crisis to its aftermath and resolution.

Improving Government Efforts

Local, state, and federal governments play a vital part in crisis management, which is considered one of the primary roles of government. Emergency services, such as fire and police departments at the local level and the U.S. National Guard at the federal level, often play integral roles in crisis situations. To help coordinate communication during the response phase of a crisis, the U.S. Federal Emergency Management Agency (FEMA) within the Department of Homeland Security administers the National Response Plan (NRP). This plan is intended to integrate public and private response by providing a common language and outlining a chain of command when multiple parties are mobilized. It is based on the premise that incidents should be handled at the lowest organizational level possible. The NRP recognizes the private sector as a key partner in domestic incident management, particularly in the area of critical infrastructure protection and restoration. The NRP is a companion to the National Incident Management System, which acts as a more general template for incident management regardless of cause, size, or complexity. FEMA offers free Web-based training on the NRP through the Emergency Management Institute. Common alerting protocol (CAP) is a relatively recent mechanism that facilitates crisis communication across different media and systems. The CAP helps create a consistent emergency alert format to reach geographically and linguistically diverse audiences through both audio and visual media.

Total Crisis Management

A comprehensive approach to implementing continual improvement in crisis management is adopting principles and practices similar to that of total security management (TSM). TSM is the business practice of developing and implementing comprehensive risk management and security practices for a firm's entire value chain. This business strategy seeks to create added value for companies by managing security and resilience requirements as core business functions as well as to enhance asset management, increase brand

U.S. Air Force members of Operation Tomodachi coordinate gear at Sendai Airport, Japan, on March 16, 2011. The 353rd Special Operations Group, the U.S. military's humanitarian and relief effort in response to the 9.0-magnitude earthquake and tsunami that struck Japan on March 11, 2011, established a usable runway at the airport. For many relief organizations, the tsunami was an event that became a source of lessons learned in order to determine best practices for future events.

equity and goodwill, and improve preparedness and resiliency. The TSM name borrows from the management concept Total Quality Management (TQM), an approach made famous by the work of W. Edwards Deming. The TQM concept revolutionized the manner in which quality was perceived in industry, encouraging it to be integrated into the core business processes of a firm. A company or agency using the TSM methodology utilizes a framework of focus points, metrics, and feedback loops in order to elevate risk management from a noncore objective to an essential business function. This process includes establishing and creating a compliance management plan, implementing operational processes, evaluating the effectiveness of operational plans, making appropriate changes as necessary, sharing successful lessons learned with internal and external stakeholders, and pursuing continual incremental improvement.

On December 16, 2009, the U.S. Securities and Exchange Commission (SEC) approved Rule No. 33-9089, which went into effect on February 28, 2010. This rule requires companies to increase their reporting of risk management practices, including details about the manner in which risk oversight is administered. The ruling has generated increased interest in implementing the TSM approach to ensure compliance with the updated SEC guidelines. In January 2010, the International Organization for Standardization (ISO) 28000 was updated to include an explicit reference to the Plan-Do-Check-Act model of quality management popularized by Deming.

Applying Best Practices

The term *best practices* refers to a set of principles and guidelines about the process and content of crisis management, including methods, skills, new technologies, training, drills, exercises, and other relevant information resulting from advances from scientific discovery, findings from case studies and field research, and lessons learned from actual crises and disasters. There is a high degree of consensus among practitioners and scholars, as well as supporting scientific evidence, that these methods and techniques are highly effective in responding to crisis. For example, a case study that reveals advances in warning systems, training, drills, and improvements in preparation for and response during and after a crisis often can set a standard for a best practice for crisis management. Recent developments that have provided guidance on best practices for crisis management are rapidly growing scientific literature, analysis and consolidation of practitioners' cumulative experiences, and the allocation of significant resources by government agencies and the private sector to improve crisis management. Recent sources for best practices incorporate lessons learned from events such as the tsunami in Japan in 2011, Hurricane Katrina in 2005, the transportation system bombings in London in 2005, the tsunami in the Asia Pacific region in 2004, the SARS outbreaks of 2003, and the terrorist acts of September 11, 2001.

The best practices framework is practice driven and seeks to blend the experiences of those who implement or engage in risk and crisis communication across a variety of circumstances and populations. However, scientific theories and strong evidence derived from systematic inquiry also inform best practices. Moreover, best practices should be considered works in progress because new evidence is forthcoming and lessons learned from real-world events are ongoing. The most useful sources for best practices acknowledge their tentative nature. They caution that many of the principles will be refined as events and evidence dictate and as new or emerging risks present opportunities for learning.

Continuity of Government

Continuity of government (COG) is the principle of establishing defined procedures that allow government, at all levels, to continue its essential executive, legislative, and judicial operations and functionality in the event of a catastrophic event or conflict. Modern COG planning can be traced back to World War II–era Great Britain. COG planning grew and evolved throughout the Cold War and is still a relevant and essential function in the era of weapons of mass destruction proliferation and global terrorism.

COG planning is a common practice internationally. Canada, Sweden, France, Norway, the United Kingdom, and numerous other countries across central and Western Europe are known to have active COG planning initiatives. Because of the sensitive nature of these plans, very little information is readily available to the general public regarding plan specifics, especially among former or current adversaries.

In the United States, COG planning dates back to at least the Cold War and has its roots in the National Security Act of 1947; it remains a top priority in the post-9/11 era. Throughout their history, continuity of government plans have been completely or partially classified to prevent an adversary from using the information contained in the plans as a blueprint for attack, sabotage, or propaganda. Early continuity of government planning was designed to ensure that the government of the United States would be able to continue operating after a catastrophic national emergency, including nuclear conflict. Modern planning initiatives have seen the addition of micro or targeted threats to the macro threat of global nuclear conflict. To date, the United States COG plan, or Continuity of Operations Plan (COOP), has been activated only once. Regardless of era, a common theme of all COG planning is the need to provide an organized and legal model for the transition of power and responsibilities during times of crisis, while keeping the society as close to normal as possible.

Leadership and Authority Delegation

Order of leadership succession must be strictly defined at all levels of government to avoid unlawful transitions or consolidations of power and facilitate a smooth transition of power. Although succession orders at the local or municipal levels can often be accomplished with a simple organizational chart, state and federal governments require codified legislation due to the complexity and scope of government at these respective levels. There are often similarities between state and federal orders of succession, as illustrated in the order of succession for the office of president of the United States of America:

1. Vice president
2. Speaker of the House of Representatives
3. President pro tempore of the Senate
4. Secretary of State
5. Secretary of the Treasury
6. Secretary of Defense
7. Attorney general
8. Secretary of the Interior
9. Secretary of Agriculture
10. Secretary of Commerce
11. Secretary of Labor
12. Secretary of Health and Human Services
13. Secretary of Housing and Urban Development
14. Secretary of Transportation
15. Secretary of Energy
16. Secretary of Education
17. Secretary of Veterans Affairs
18. Secretary of Homeland Security

A sample order of succession for the office of governor is as follows:

1. Liutenant governor
2. President of the Senate

3. Speaker of the House
4. Whoever is highest ranking among the following offices and is eligible to serve as governor:
    a. Secretary of State
    b. Auditor
    c. Treasurer
    d. Superintendent of Public Instruction
    e. Attorney general
    f. Commissioner of Agriculture
    g. Commissioner of Labor
    h. Commissioner of Insurance
    i. Commissioner of Public Safety

A sample order of succession for the office of town or city mayor is as follows:

1. Vice mayor
2. Town or municipal council designee

A sample order of succession for the office of town or city manager is as follows:

1. Assistant town or city manager
2. Public works director
3. Police chief
4. City attorney

Specific statutes and laws differ from state to state regarding legal requirements for the office of governor, so individual state succession plans will vary as well, especially in states where individuals are permitted to serve in cabinet-level secretary or commissioner offices while not meeting the requirements or eligibility for the office of governor.

Delegation of essential functions and authorities should be clearly identified at all levels of government, cabinets, and departments as a contingency for the loss of leadership or the reassignment of leadership. All eligible leaders or personnel in a line of succession must have a baseline level of training to allow them to function in their acting role during a catastrophe.

Continuity of Leadership

A common trait among the most successful government entities and organizations is a sustained operating philosophy of a period of years, or even decades. Leaders at all levels of an organization or entity are custodians of this philosophy and are responsible for maintaining not only a prescribed level of performance but also a way of doing business or conducting operations in order to support the stated goals. Sustaining a standard of excellence over an extended period of time is only possible through continuity of leadership.

Information and Data Surety

Information surety in the context of GOG planning is the safeguarding of vital records, databases, operational computer systems, and other related essential information sources and systems. Governments at all levels maintain a variety of vital records that are invaluable during a catastrophic event. These records contain information such as population demographics, financial and tax bills for local businesses, and legal documents. These data sets, along with many others, provide an essential snapshot of populations, resources, and potential impacts at the local, state, regional, and federal levels. These records and their associated information are also essential to maintaining order during crisis and provide the foundation for recovery and resumption of normal activities. On a more tactical level, response- and defense-oriented networks must also be preserved during a catastrophe to preserve a nation's ability to provide for defense as well as assist in response and recovery.

Communications

Because of the nature of COG planning and operations, many different agencies from a geographically diverse area often come together as response partners. A core principle of COG requires that key decision makers be securely isolated from threats, and under certain circumstances from each other, in order to preserve the order of succession. While leaders and officials may be isolated from their departments or constituency, they must still be able to communicate in a reliable and timely manner.

Issues related to achieving interoperable communications have been documented as far back as the Oklahoma City federal building bombing in 1995. Interoperable communications continue to pose a challenge today, and communication capacity and redundancy are major issues as well. In many ways, solving the interoperability issues of the late 1990s has decreased the data capacity and redundancy of today's digital communications infrastructure.

Modern COG plans must feature communications annexes that provide for common operation but also must be have the capacity to handle double or triple the normal traffic volume or bandwidth. Additionally, as governmental agencies, private response partners, and the U.S. military start narrow-banding along the 700–800 MHz range, alternate redundant systems are still needed. These alternate systems can include narrow-banded Ultra High Frequency (UHF) and Very High Frequency (VHF) radios, as well as secured cell phones.

Above all else during a continuity of government emergency, communications must remain secure. The most diligent COG plans in the world can be rendered useless if communications between command centers and field personnel or forces are compromised, jammed, or hijacked. Communications security during a catastrophe can include a variety of measures ranging from encrypted devices, to frequency hopping or frequency skipping transmitters, to coded or cipher-based messaging. Although the latter is in direct

Case Study 1: Continuity of Government Following September 11, 2001

On September 11, 2001, the United States suffered nearly simultaneous terrorist attacks on New York City and the Pentagon, the nerve center of the Department of Defense (DoD). The National Continuity of Operations Plan was activated for the first time. The plan implementation involved the president, the vice president, up to 150 senior officials and other government workers from numerous federal departments, and other key personnel from the executive branch and legislators moving to secure locations across the country. The president, in Florida at the time of the attacks, was taken to several high-security military facilities before eventually returning to Washington, D.C. In an effort to preserve the order of succession to the office of president, several of the individuals immediately behind the vice president in order of succession were taken to separate secure locations.

Additionally, in Big Sky, Montana, more than 350 government officials and contractors were attending an emergency response conference at the time of the attacks. They included the director of the Federal Emergency Management Agency; officials from the Commerce Department, the National Oceanographic and Atmospheric Administration, and the DoD; and numerous state emergency management/civil defense directors and governors. Over the next few days, the officials in attendance, from all levels of government, struggled to establish communications and obtain situational awareness from their home offices or jurisdictions.

Although numerous exercises had been held over the years to test key functions, and at times even the entire continuity of government plan, the 9/11 attacks highlighted several issues and performance gaps to include a lack of interoperable and real-time communications between the private sector, governmental entities, and at times the DoD.

In the years following the attacks, contingency planners and agencies have sought to address these and many other challenges, with interoperable communications and multijurisdictional coordination being a primary focal point. Since its formation, the Department of Homeland Security has conducted several exercises to test continuity plans and measure the efficacy of these and other planning and performance improvement initiatives.

The United States has been in a state of national emergency continuously since September 14, 2001, when the Bush administration invoked the National Emergency Act in response to the attacks. The act, which grants various powers to the president during times of emergency and was intended to prevent a president from declaring a state of emergency of indefinite duration, must be renewed every two years. The act remains in effect, following an extension by President Barack Obama in September 2011. This underscores the gravity and complexity that COG planners face.

conflict with initiatives by FEMA and others to move away from "coded messaging," in the absence of any other method of securing communications, it must be considered.

Alternate and Contingency Facilities

Secured contingency operations centers are essential to support COG plans at all levels of government. These locations and facilities fall under one of two categories: hot sites and cold sites. Hot sites are facilities that are fully staffed and networked at all times. These facilities can host emergency or contingency operations at a moment's notice or as soon as the designated executive or decision makers arrive on site. Cold sites, by contrast, are fully capable operations centers but are not permanently staffed or ready for operations. These facilities can be brought online within a predetermined period of time after notification. Although cold sites are not staffed at all times, there is a maintenance and sustainment component to each every cold site that ensures operational and logistical readiness.

At the federal level, successful COG planning must utilize a combination of hot and cold sites in order to achieve optimal resiliency. State and local governments often lack the resources and finances to support multiple hot sites and typically rely on a single hot site with several alternate cold sites. For security reasons, the locations, classifications, and capabilities of all operations centers, hot or

Case Study 2: Continuity of Leadership in College Athletics

College athletics, specifically basketball, can be used as a model continuity of leadership model for nearly every level of organizational leadership. The lessons learned from a close analysis of two of the most successful NCAA Division I basketball programs over the past 30 years, the University of North Carolina and Duke University, are applicable to both everyday and crisis management models.

Longevity Versus Transition

A single entrenched leadership over a period exceeding 30 years does not guarantee success in the same way that four different leaders in 30 years does not guarantee failure. In the cases of Duke University and the University of North Carolina basketball programs, both scenarios have resulted in unrivaled success over the past two decades. In the case of Duke, the program has achieved four national championships, 13 Atlantic Coast tournament titles, and 12 Atlantic Coast regular season titles under a single head coach, Mike Krzyewski. In contrast, the University of North Carolina has achieved four national titles, eight Atlantic Coast tournament titles, and 15 Atlantic Coast regular season titles under four different head coaches, Dean Smith, Bill Guthridge, Matt Daugherty, and Roy Williams.

Recruiting and Retaining Leadership

At first glance, it is easy to assume that both programs' sustained success is a factor of superior "executive leadership" and attracting superior athletes; however, in both cases, both programs have sustained an elite level of operational leadership among their players. This, by far, is the most important and impressive attribute of both programs, especially considering the context of the NCAA student athlete. Student athletes are eligible to participate with a school for a period of one to four years; under certain circumstances, this eligibility can be extended to a fifth year. This requires coaches to recruit established, capable leaders, as opposed to developing them over a period of several years. Additionally, every athlete must be a leader, not just the captains. An elite athlete does not necessarily equal an elite leader.

Attracting the right talent is only half the battle. Both programs also excel at retaining talent at both the executive and operational levels. In a sport where many players stay in college only one year before leaving to pursue professional careers, both schools routinely have rosters stocked full of upperclassmen. This sustained pipeline of leadership has ensured that both programs have enjoyed systemic success with only episodic setbacks.

cold, are classified to the highest degree appropriate. Over the years, several locations in the United States have been confirmed to be former or active contingency operation centers. These sites include:

- Cheyenne Mountain, Wyoming: The home to North American Aerospace Defense Command (NORAD) and U.S. Northern Command (USNORTHCOM)
- Mount Weather, Virginia: FEMA Emergency Operations Center

In addition to fixed facilities, mobile platforms such as Air Force One and the National Airborne Operations Center are tasked with being mobile contingency and command platforms. During the 1960s, mobile platforms also included the National Emergency Command Post Afloat (NECPA), the USS *Northampton*, and the USS *Wright*.

In addition to contingency operations and command centers, governments and private-sector entities must also maintain alternate locations to ensure data protection and communications redundancy. Much like operations centers, these alternate facilities are classified as hot or cold facilities. It is common for such facilities to be present at the national or military level. Because of financial and logistical limitations, state redundancy sites are typically limited contingency communications relays for statewide radio systems. Very few city or county governments have resources to develop or maintain redundancy locations, outside a limited capacity redundant data center. City and county governments will, however, on occasion partner with the private sector to develop regional solutions for very targeted and narrow-scope systems.

Cooperative for Assistance and Relief Everywhere (CARE)

CARE International is a large nonprofit confederation of national members in 12 countries. CARE brings humanitarian aid to developing countries and provides help spawn social and economic progress. CARE began through a group of American organizations wanting to aid post–World War II Europe. Its base broadened so that it became a multinational nonprofit. CARE moved from delivering packages to providing other kinds of relief, education, and advocacy. CARE is one of the most respected charities in the world.

CARE was formed in the United States in November 1945 as the Cooperative for Assistance and Relief Everywhere to meet the needs of poverty-stricken people in post–World War II Europe. The organization was the effort of 22 organizations seeking to aid those in Europe. The initial efforts of CARE involved the sending of CARE Packages. The initial packages were boxes of surplus meals that had been intended for the U.S. Armed Forces who were to have invaded Japan. For $10, a box could be sent to someone who needed food in Europe. Later, CARE put together its own boxes of food, and individuals did not have to know the individual to whom the box would be sent. Eventually, the boxes of food were modified to account for the culture of the recipients, and food was supplemented with other needed items like medicine and blankets. In 1953 the organization modified the meaning of CARE to Cooperative for American Relief Everywhere. CARE Packages were sent to Europe until 1955. Thereafter, the packages were delivered to other developing parts of the world. In 1968, CARE suspended the delivery of packages, although there were some instances in which packages were sent to limited areas. Approximately 100 million CARE Packages were delivered by the organization.

CARE International was formed and became the umbrella organization for member countries. The CARE International secretariat, or headquarters, is located in Geneva, Switzerland. The secretariat has an office in New York to work with the United Nations and one in Brussels to work with European entities. In addition to the 12 national offices, there are CARE offices in many of the countries where CARE has ongoing projects. Each of these country offices is led by a country director. The secretariat, along with the board of directors, coordinates the work of national affiliates, sets policies, and helps coordinate responses to humanitarian crises. The secretariat also houses the CARE Emergency Group, which enables the organization to act quickly in emergencies that standard programs are not equipped to handle or that happen in locations where there is no CARE presence.

As CARE International has evolved, it has shifted its emphasis to fighting poverty and addressing health issues in the developing world. Empowering women is at the heart of its community-based work to provide education in health, sanitation, and economic opportunities. CARE deems girls and women as the most effective agents of change in society. The ripple, or butterfly, effect of helping one and seeing that help impact others is at the core of CARE's philosophy. CARE also provides emergency relief services to those impacted by human-made or natural disasters. CARE seeks long-term solutions to poverty issues. Sustainable food production is one of those issues. The organization works with many communities to help design effective ways to produce food for the residents. Projects are developed to help families produce more food from the land and also stress conservation of the natural resources that are crucial for continued productivity and for a healthy ecology. CARE also works to help food producers get their produce to markets. CARE advocacy includes issues related to climate change, women's empowerment, poverty alleviation, and influencing funding policies of governments related to these and other important issues.

CARE International's national affiliates are located in the following countries:

- Australia
- Austria
- Canada
- Denmark
- France
- Germany-Luxembourg
- Japan

- Netherlands
- Norway
- Thailand
- United Kingdom
- United States

CARE works with partners at local, national, and international levels. Through local partnerships with nongovernmental organizations (NGOs), and even informal locally based organizations, CARE is able to better assess the needs of the community and draw on the skills and resources of the locals. CARE is also able to add value to these local groups through training and the experience these groups gain. CARE also works through local schools and with medical personnel. At the national and international levels, CARE seeks, along with like-minded organizations, to influence government policies and funding for areas of joint concern.

In 2010, CARE USA had total income of $634 million. Approximately $525 million was spent on CARE programs during the year. Half of program funds were spent in Africa, 21 percent in Asia, 16 percent in Latin America and the Caribbean, and 13 percent in Europe and the Middle East.

In 2011, CARE International had a total of 1,015 projects in 84 countries around the world. In the months after the 2010 earthquake in Haiti, CARE provided emergency relief for 290,000 people. In that same year, 91 percent of CARE's expenses were for programs and 9 percent of the budget was spent on fund-raising and administrative costs. Also that year, 77 percent of program expenses were directed toward long-term poverty issues and 23 percent toward emergency and rehabilitation help. CARE has a Humanitarian Accountability Framework, which is a statement of the organization's desire to provide humanitarian work that is of high quality. The statement provides CARE staff with a guide to providing the kind of service desired by the organization. CARE has a system that ensures its processes, outcomes, and impacts. This ensures that lives are being impacted through the use of resources the organization has at its disposal. CARE seeks to involve impacted communities in this assessment process.

Coordination

Coordination in crisis and emergency management indicates the partnerships involving government, business, nonprofits, communities, and the public as a whole working toward mutual goals. Actually, interorganizational cooperation is a widely held ideal shared by many emergency agencies in many societies. Coordination is most likely to be achieved when organizations have pre-disaster connections, a willingness to work together to meet emergency management needs, and appropriate communication methods.

Multiorganizational coordination is essential for crisis and emergency management. Traditionally, individuals and local communities take the main role of disaster response because natural disasters are seen as the action of God. But disaster preparation and response is widely viewed as the appropriate role of government by most citizens in recent years. They expect the government, especially their local government, to take an active role in disaster and emergency management. As the emergency management department in the government is relatively small, and less powerful, a coordination and collaboration between different agencies is necessary for effective emergency response. Also, the nonroutine nature of disasters does not require a large number of full-time employees in an emergency management department, but once a major incident happens, a large amount of personnel and resources both inside and outside an emergency management department are needed and thus require multiorganizational coordination. What's more, the disruptive and dynamic nature of disasters—the negative effects of disaster always beyond the response capacity of local communities—also requires multiorganizational coordination. Finally, research evidence has proven that the command-and-control model for disaster management is flawed, and a coordination-and-collaboration model is more suitable for disaster and emergency response. Because no single department or agency has sufficient resources to deal with large-scale disaster at hand, a close working relationship and coordination among different organizations is necessary for effective and efficient disaster response, recovery, and prevention.

Most current disaster and emergency laws and policies require a multiagency coordination model. For example, in the United States, nearly all the emergency-related laws, like the Robert T. Stafford Disaster Relief and Emergency Assistance Act, the Homeland Security Act, and the Post-Katrina Emergency Management Reform Act of 2006, encourage a coordination work model—the Federal Emergency Management Agency (FEMA) is required to work with state, tribal, and local governments; the private sector; and nongovernmental organizations (NGOs) to facilitate inclusive, multiagency, community-wide, and coordinated response and recovery effort.

In order to implement the coordination mission, several temporary or permanent organizations or positions are created. At the local level, the local emergency operation center (EOC) is the physical location where multiagency coordination occurs. The EOC can be a permanent or temporary organization directed by a full-time emergency manager or an appointed official. The state emergency operation center (SEOC) is the physical location where multiagency coordination happens at the state level. A joint information center (JIC) may be established to coordinate emergency information and other public affairs functions. The state coordinating officer (SCO) is the key person in charge of state response and recovery implementations after a disaster declaration. A joint field office (JFO) and unified coordination group (UCG) may be formed with officials from all related agencies, as well as representatives from nongovernmental organizations and the private sector. At the federal level, the National Operation Center (NOC) is the primary national hub for multiagency coordination across different federal agencies for emergency management. Unlike the EOCs at the state or local level, the National Operation Center is a continuously operating multiagency operation center.

The National Incident Management System (NIMS) in the United States was developed from the Incident Command System (ICS) and the Standard Emergency Management System (SEMS) and is a set of systems designed to standardize disaster response for effective, efficient, and collaborative incident management. It seeks to improve post-disaster operations through predisaster planning and capacity building. The NIMS not only is designed to improve interagency coordination between all levels of government but also covers all other types of responders, including private-sector and nonprofit organizations.

Intergovernmental Coordination

Two primary government systems provide examples of the following types of intergovernmental coordination: federalism and centralization.

Federalism: Federalism countries like the United States reflect the philosophy of separating the functions of government and allowing some degree of sovereignty at lower levels of government. The emergency management systems in these countries also reflect such a federalist natural. For example, localism, lack of standardization, unit diversity, and fragmentation are the main features of the American emergency management system, according to Thomas Drabek's observation of six major disasters over a two-year period. Coordination and collaboration is the principal way to deal with disaster and emergency management issues between different levels of government and varied agencies. The policies and organizations introduced above reflect the main part of hierarchical coordination in countries like the United States.

Memorandums of Understanding (MOUs) and mutual aid agreements are common means to strengthen the interagency, intersectoral, or interjurisdictional assistance and coordination. The difference between the two is that mutual aid agreements are more formal than MOUs.

Case Study: Walmart's Coordination Efforts During Hurricane Katrina

Walmart's response to Hurricane Katrina, which hit the coast of Louisiana on August 29, 2005, is a case study in public- and private-sector coordination. Immediately after the incident, Walmart initiated its emergency operations. Walmart's quick response to the hurricane showed good coordination with government at all levels, nongovernmental organizations, communities, and other private-sector companies. It also demonstrated good inner-corporate coordination.

From the beginning of the event, Walmart's chief executive officer (CEO) made it clear that all operations relative to the preparation for, response to, and recovery from the hurricane were to flow through their emergency operation center (EOC). Departments and divisions that had business unit representatives located within the EOC served as decision makers and liaisons for their respective business units. The EOC quickly developed and passed a situational awareness plan and formed a whole image for the business unit representatives there. The business unit representatives then made decisions on strategies and tactics based upon the big-picture data that had been collected. Walmart grouped its available resources into restoration, energy, systems, security, and management teams according to their skill and technology advantages to perform tasks of searching for lost employees, assessing facilities, reconstituting and restoring operations, and coordinating with government officials.

During Hurricane Katrina, Walmart coordinated closely with local agencies and communities to provide support to the victims. The restoration, energy, systems, security, and management teams worked to recover operations and mitigate further loss. The security teams worked with law enforcement agencies and the National Guard to ensure safety. They talked with the Centers for Disease Control and Prevention and state health agencies to develop health strategies. They also provided vaccinations and pharmaceuticals to emergency workers. The management teams reopened the facilities, supported hospitals and communities, and sheltered police officers and emergency services workers in their stores. The energy teams started designated generators to provide power to facilities in areas that did not have power for days and weeks. They provided generator support to power other facilities such as hotels, water treatment plants, and hospitals. Information systems teams established network and voice connectivity by setting up temporary satellite systems. Over the next few days, Walmart provided $20 million in donations, 1,500 truckloads of merchandise, food for 100,000 meals, and the promise of a job for every displaced worker.

Through a coordinated response and dedicated employees, Walmart's efforts were widely regarded as one of the most successful of all corporations in the aftermath of the disaster and set the standard for future corporate disaster relief programs.

FEMA defines the mutual agreement and assistance agreements as "agreements between agencies, organizations, and jurisdictions that provide a mechanism to quickly obtain emergency assistance in the form of personnel, equipment, materials, and other associated services." The primary objective of the mutual aid agreements is to facilitate rapid, short-term deployment of emergency support prior to, during, and after an incident. The Emergency Management Assistance Compact (EMAC) that allows states to assist one another in all kinds of disaster response is the most common interstate mutual aid agreement. It is administered by the National Emergency Management Association (NEMA) and mainly contains the Interstate Mutual Aid Legislation Model and State-County Mutual Aid Deployment Contract Model.

Centralization system: Some countries like China have a more centralized government system than a federalism regime. The emergency management systems in these countries also reflect a much stronger centralization and the coordination capacity of the central government. In 2008, a devastating earthquake hit southwest China and caused thousands of deaths. The central government responded to the catastrophe very rapidly and won praise from the public. Also, with the strong coordination of the central government, a widely covered state-county mutual aid model was implemented for disaster recovery, and this method has proven to be especially helpful. However, this top-down method is not useful for most incidents because the central government cannot be involved in most disasters.

Public and Private Coordination

In most countries, the private sector owns the majority of infrastructure and provides most products and services to the public. Also, private contractors play an important role in the disaster and emergency area. For example, many private contractors take the responsibility of debris cleaning after a major disaster. Increasing evidence indicates that coordination and collaboration between public and private sectors could improve the community's capacity to prepare for, respond to, and recover from disasters.

In the United States, the Private-Sector Coordination Support Annex of the National Response Framework is the main policy guidance for public-private coordination activities. Except for the organizations mentioned in the coordination section, some other organizations like the Private Sector Office (DHS/PSO), Office of Infrastructure Protection (DHS/OIP), and National Infrastructure Coordinating Center (NICC) are specified as the public-private coordination organizations. Private-sector organizations are required to take responsibility for their internal preparedness, including risk identification and assessment, contingency and emergency planning, etc. They are also encouraged to accept responsibilities such as information sharing with government, goods and service provision through contractual arrangements or government purchases, and pro-social behaviors (donations and volunteerism) provision like corporate citizens.

Public and Nonprofit Coordination

Voluntary agencies have a long and proud tradition in disaster response and relief work in the United States. Back in 1736, Benjamin Franklin created the first volunteer firefighting company in Philadelphia, and this was recognized as the first voluntary agency involved in disaster response work in America. Voluntary agencies are agile and less bureaucratic than government agencies, and they play a critical role in all phases throughout the disaster cycle: mitigation, preparedness, response, and recovery. However, nongovernmental organizations have limitations in resources, accountability, and coordination, and this weakness can undermine their effectiveness and efficiency as well as equitable distribution of services. Also, the preference of donors, such as that they may be more interested in immediate disaster relief rather than longer-term recovery and mitigation, can also cause problems in maximizing the outcome. Thus, the voluntary sector alone cannot guarantee a just and effective social response to disasters, but it will inevitably work alongside the government.

The Volunteer and Donations Management Support Annex is the main guidance that describes the coordination processes used to support the state in ensuring the most efficient and effective use of unaffiliated volunteers, unaffiliated organizations, and unsolicited donated goods. It states clearly that the federal government encourages state, tribal, and local governments to coordinate with volunteer agencies, community and faith-based organizations, volunteer centers, and private-sector entities through local Citizen Corps Councils and local voluntary organizations active in disaster (VOAD) members to participate in disaster preparedness activities. Also, the Emergency Support Function #6, Mass Care, Emergency Assistance, Housing, and Human Services Annex of the National Response Framework provides guidance of mass care and disaster relief in the United States. At the regional level, FEMA has Voluntary Agency Liaisons (VAL) to develop the relationship between FEMA regional offices and voluntary agencies. It plays a main connection and coordination role between federal agencies and nonprofit organizations.

The following two examples demonstrate public and nonprofit coordination:

American Red Cross and government coordination: The American Red Cross is a humanitarian organization led by volunteers and guided by its Congressional Chart and the Fundamental Principles of the International Red Cross Movement.

It has been a primary disaster relief organization that helps people prevent, prepare for, and respond to emergencies for more than 100 years in the United States.

After Hurricane Katrina, about 250,000 Red Cross workers, 95 percent of whom were volunteers from all states and territories, responded to provide services, including sheltering, food, health and emotional care, and relief supplies, to more than four million people. But the mass care needs of this catastrophe exceeded the capacity of the Red Cross. Some groups criticized the Red Cross for not providing timely mass care due to poor coordination with FEMA—they could not get access to the target victims in some areas. So, the role of the American Red Cross as a "primary agency for mass care" (2004 National Response Plan) was changed to a unique federally designated role as a "support agency to FEMA for mass care" (2008 National Response Framework).

NVOAD/VOAD and Government Coordination: National Voluntary Organizations Active in Disaster (NVOAD) was created in 1970 by seven voluntary agencies active in disasters to meet coordination needs during crises. It is a forum comprising about 50 national members and 55 state and territory equivalents with the mission of sharing knowledge and resources throughout the disaster cycle to help disaster survivors and their communities. In 1979, soon after FEMA was established, the directory of FEMA met with NVOAD membership, and then the NVOAD appointed a committee to work closely with FEMA as a response. Now, FEMA participates actively in NVOAD's board meetings, committee meetings, annual meetings, and the Annual VOAD Leadership Conference. Additionally, FEMA maintains Memorandums of Understanding with individual voluntary agencies and works closely with NVOAD members individually. Through these agreements, FEMA provides financial support, training, and public relationship development to NVOAD and VOAD members, and NVAOD encourages information sharing between members and public sectors as a response.

Coping Capacity and Response Capability

Crisis events present challenges to people that fall well outside the realm of normal human experience, possibly for periods of time that can range from months to years, decades, or a lifetime. This circumstance can thus require the development of new coping and response mechanisms to supplement or complement those used in more routine contexts. Furthermore, large-scale crisis events, such as natural disasters and acts of terrorism, impact people, affect communities, and disrupt the societal mechanism people normally rely on to cope with the demands of everyday life. Under normal circumstances, people are generally unaware of how interdependencies between themselves and community and societal processes (e.g., economic, cultural, political) influence how they cope with the demands of daily life. However, crisis events that create wholesale disruption across all levels of society throw these interdependencies into sharp relief and highlight a need to accommodate them within a comprehensive definition of crisis coping capacity and response capability.

The challenging and often enduring nature of crisis events results in people's knowledge and resources being insufficient or inappropriate for successful coping. People thus find themselves needing to rely not just on themselves but also on information, resources, and guidance provided by their social networks and government and nongovernmental agencies. Effective coping and response thus becomes a function of the degree to which personal, community, and societal factors interact effectively.

Effective crisis coping and response capability comprises three separate but related elements. The first is possessing the resources (e.g., knowledge, skills, financial) required to adapt to disruption and losses. The second is having the competencies necessary to identify, mobilize, organize, use, and, if necessary, obtain these resources. Finally, it is pertinent to identify the mechanisms that operationalize personal, community, and societal interdependencies to provide a comprehensive capacity to respond. This article starts with people's contribution to coping with crises.

Personal Factors

The knowledge, skills, and resources people bring to crisis events influence their coping efforts. However, the ability of people to use them in novel circumstances is influenced by the psychological competencies and beliefs they use to apply their resources to help them adapt. This is illustrated using the constructs of locus of control, outcome expectancy, self-efficacy, coping, and hardiness.

People differ with regard to their personal control beliefs. People with a high internal locus of control believe they can influence what happens to them. Such control beliefs increase the likelihood of people taking action to effectively cope with crises. In contrast, people with more fatalistic control beliefs (external locus of control) believe that life events impose themselves on them, making them less likely to take actions to cope with crisis events. Coping is also influenced by differences in how people think about events and their consequences. This is labeled outcome expectancy or response efficacy.

People who hold positive outcome expectancy beliefs differentiate between events and their personal and community consequences. This cognitive attribute predisposes people to look for ways in which they might cope with the consequences. In contrast, negative outcome expectancy arises when people believe that if the causes of a crisis are beyond their control, so too are the consequences. Such beliefs undermine coping efforts. Coping is also influenced by people's beliefs regarding their personal capacity to respond to events. This is encapsulated in the concept of self-efficacy.

As people accumulate successes in dealing with challenging events in everyday life, their self-efficacy increases. Self-efficacy increases the number and quality of plans people develop to address issues. It results in higher levels of effort and persistence in actions performed to achieve goals under challenging circumstances. In contrast, people whose life experience is characterized by relatively more failures can develop a sense of learned helplessness that hinders coping and response efforts.

Coping and response efforts are also influenced by the coping strategy used. People who use problem-focused strategies tend to confront the issues and demands they face directly (e.g., finding out about problems and developing strategies to manage them). In contrast, people who adopt emotion-focused strategies focus on expressing the emotions triggered by the crisis rather than confronting the causes of the emotions. In general, problem-focused coping facilitates more effective coping and response to crisis events.

Coping and response is influenced by hardiness. Hardiness describes people whose approach to life is characterized by high levels of commitment, control, and challenge. Commitment describes their being immersed in family, work, and community life, whereas control involves perceived control over challenging events (see internal locus of control above). Challenge is a predisposition to perceive life events as challenges rather than as threats. Such people accept that change is a normal facet of life and respond to challenges in flexible ways.

The beliefs and competencies described above increase people's ability to use resources to more effectively cope with and respond to crises. However, given the extraordinary circumstances in which they can find themselves, people may need additional competencies and resources, information, and guidance. These can be obtained from community and societal sources.

Community Influence on Coping

Faced with complex and uncertain crisis events, and when lacking all the information and resources they need to make informed decisions, people turn first to those who share their interests and values for the information and guidance they need to help them decide what to do to cope with atypical, challenging circumstances. These others can be family members, neighbors, and members of the communities (e.g., workplaces, social clubs, churches, etc.) with whom people interact regularly. They can also include representatives of civic agencies (e.g., emergency management, local government). Consequently, community and civic sources can contribute to people's coping capacity and response capability. In the context of the uncertainty associated with crisis events, the quality of these interactions will influence how people cope with and respond to crisis events.

Participating in community activities provides access to information from people likely to share one's interests, values, and expectations. Consequently, information from community sources can facilitate people's ability to understand crisis circumstances and to decide what to do. Regularly participating in activities with like-minded people provides access to additional and potentially more comprehensive knowledge, skills, and resources than the person would normally possess. However, realizing the benefits of having access to a wider range of resources is a function of the presence of several additional competencies that facilitate people's ability to use them.

The utility of collective expertise is a function of the degree to which communities seek to include all members and the degree to which people actively participate in community activities (the community competence construct includes measures of inclusivity, participation, and social support). This illustrates mechanisms that operationalize the interdependencies between people to create a coping and response capability in which the whole becomes greater than the sum of its parts. However, while participation provides access to a wider pool of knowledge and expertise, deciding how to use this asset to deal with unfamiliar crisis events and identifying resources not currently available within community contexts, but required if people are to cope, requires additional competencies. These include identifying the specific implications crises have for them and where they live and work, in addition to what can be done to manage consequences.

Collective efficacy describes community members' ability to assess their capabilities and resource needs in relation to challenging tasks, define their goals, and develop plans for using resources to achieve goals. Community competence includes components that describe how coping and response to crisis events can be facilitated if community members can articulate their problems and needs and possess mechanisms that assist them to represent their needs to the societal agencies and businesses that can provide the information and resources they need to enact their plans and adapt effectively. Comprehensive coping and response capability does not end here.

Given the atypical nature of the demands posed by crisis events, community deliberations could identify new information and resource needs that cannot be met within existing community contexts. Being able to articulate and represent those needs to the agencies and businesses that can meet

Relief workers give medical supplies to community members along flooded routes during the unusually heavy 2011 monsoon season in regions of Thailand, which caused the worst floods in 50 years. According to Nuttapong Wongjindanon, a Centers for Disease Control and Prevention epidemiologist, community members demonstrated coping capacity despite been frustrated: "There are still signs of people sticking together and helping each other out.... People should not just wait for help from local authorities."

these needs is important. However, if agencies and businesses do not respond in ways that provide the specific information, advice, and resources communities need to enact plans to meet their specific needs, coping and response capability will be compromised. Consequently, effective coping and response is a function of the degree to which civic and business agencies empower people by acting toward them in ways that help meet the specific needs of each community.

Community–Societal Interdependence

Empowerment describes citizens' capacity to gain mastery over their affairs and confront crisis events by being supported by agencies rather than having solutions thrust upon them. Empowerment promotes the equitable distribution of resources (i.e., material, knowledge) in ways that facilitate the development of people's capacity to confront the local issues posed by crisis events. The quality of the relationship between people and agencies is influenced by the degree to which people believe that their relationship with formal agencies is fair and empowering (e.g., agencies are perceived as trustworthy and acting in the interest of community members). When this relationship is not perceived as fair, the consequence is a loss of trust in the agency (the source of information). Trust is thus an important determinant of the quality of any relationship in which information is exchanged and appraised, and decisions made under conditions of uncertainty.

Empowerment reflects the quality of reciprocal relationships between community members and the societal agencies that provide resources, information, and advice. The more citizens perceive

Case Study: Coping and Capabilities During the 2009 Australian Wildfires

Wildfires in southeastern Australia in 2009 created circumstances that required communities to develop new approaches to responding to and coping with the disruption and loss that occurred, including developing new relationships with communities, government, and businesses.

A need for new coping approaches arose as a result of the need to look after oneself and one's family before engaging in activities with others. Individual coping was facilitated by accessing information that advised on physical and psychological health issues that could arise and the strategies to cope with the immediate and medium-term impacts. The effectiveness of this approach was supported by developing supportive relationships within communities. This provided the foundation for securing social support and the development of community coping and response strategies to deal with community-wide issues.

The emerging approach to confront collective issues involved the development of community planning processes established to elicit and communicate information and allow people to hear about and contribute to ways of responding to their diverse challenges. These processes facilitated consultation with as many people as possible within affected communities in order to identify both the issues people faced and the coping and response strategies they could use to deal with them. Such extensive consultation led to high levels of initial participation. However, resourcing and time issues meant it was not possible to act on all suggestions. This resulted in conflicts when people felt their ideas were being ignored and threatened to disrupt effective community response. To circumvent this, members developed processes for clarifying and prioritizing issues, maintaining community integrity by making explicit the need to prioritize actions in relation to factors such as resource availability or the time it would take to act and the processes used to make these choices. A key message was stating that their not being acted on did not lessen the relevance of ideas or their possible future use.

The range of response issues necessitated developing ways of coordinating response activities. This led to the selection of leaders from within the community, with different individuals taking responsibility for different activities (e.g., liaison with government, community-building processes). Later review of this process identified the need for training and support for leaders. Letting this happen in situ reduced the initial effectiveness of the process and resulted in people's responsibility leading to exhaustion and burnout. The election of leaders was important, as it provided them with legitimacy both within the community and in the eyes of government and external businesses.

Elected leaders provided communities with a voice and connection to government and helped government see that leaders were representing the whole community. Elected leaders provided a mechanism by which bottom-up, community-generated ideas could be proactively represented to government agencies and provided a conduit for maintaining collaborative relationships with government and businesses. It also emerged that while businesses were often interested in offering assistance, they did not know how to do so. This led to the realization of the need to be proactive in dealing with the commercial sector to ensure that resources could be procured when needed.

Although the development of individual and community coping and response strategies had many benefits, it also incurred certain costs. The benefits included developing social support networks and fostering a sense of control and resilience. However, several problems emerged, including the need to accommodate differences in how people cope and the ability to meet needs that present at different times. Ensuring that members of pre-existing groups and committees were given roles and not usurped by new groups specifically associated with the crisis was important to sustaining a sense of community. It was also important to develop management and negotiation skills to manage the consultative processes. Other lessons included preventing people becoming overcommitted and neglecting personal and family needs over time, and implementing processes for membership and leader succession, limiting periods of involvement, and providing opportunities for people to withdraw if necessary.

their needs as having been met through their relationships with societal agencies and institutions, the more likely they are to trust them and the information they provide. In this way, empowerment and the trust it engenders facilitate the ability of people and communities to cope and respond to crisis demands.

The capacity to cope with and respond to atypical crisis events will not develop by chance. Developing these outcomes requires a conscious effort on the part of people, communities, and societal institutions to develop and maintain the resources and processes required to ensure that coping can happen and that it can be maintained over time. Maintaining a capacity for coping over time is especially important for infrequent threats that pose unique challenges for effective response.

Cosmology Episode

Crises are ontologically challenging events that engage individuals in a high degree of uncertainty. In severe crises, the unfolding events may unravel an individual's or group's existing beliefs about how the world works. A cosmology episode is a state of mind that occurs during one of these extreme periods of ontological distress. In a cosmology episode, an individual or individuals may lose the ability to rationally make sense of a situation. Their surroundings are no longer acting as expected, and their existing ontological assumptions are disrupted.

Karl Weick, an organizational communication scholar, introduced the term *cosmology episode* into the crisis literature from philosophy. The philosophical study of cosmology is a macroscopic view concerned with understanding the structure of the universe. As individuals engage in their daily lives, they operate under a cosmology that events will unfold in space and time in an orderly manner. When a crisis occurs, these individual or shared cosmologies are confronted with a new reality that is both unfamiliar and dangerous. According to Weick, "A cosmology episode occurs when people suddenly and deeply feel that the universe is no longer a rational, orderly system. What makes such an episode so shattering is that both the sense of what is occurring and the means to rebuild that sense collapse together." Thus, both the ability to understand the situation and the ability to use reason to create a new order are lost during a cosmology episode.

In the field of crisis management, the concept of a cosmology episode is useful for practitioners to understand how both emergency responders and the population they are helping may react during a crisis. The concept of a cosmology episode has been applied within a variety of theoretical lenses such as sense-making and chaos theory to explain the loss of rationality and the struggle for sensemaking during an overwhelming crisis situation.

Case Study: The 2002 Minot, North Dakota, Train Derailment Cosmology Episode

When a train derailed in Minot, North Dakota, at 1:30 A.M. on the still and frigid morning of January 18, 2002, approximately 250,000 gallons of anhydrous ammonia were released from the wreckage. Instead of dissipating into the atmosphere, the deadly chemical interacted with the cold temperatures and created a dense fog that settled within the community that was located below the tracks in a valley. The fog was poisonous to breathe and would burn moist areas of the body such as the eyes and lungs. Additionally, the combustion engines of vehicles were largely unable to work in the fog, so officials were very limited in direct notification, evacuation, and rescue attempts. As officials began to respond to the situation, they were confronted with several emergency notification system failures that did not allow them to get information about the derailment out to residents.

The community's small 911 system was immediately overwhelmed, and the vast majority of residents were met with a busy signal. The community's outdoor emergency sirens were activated, and a voice message instructing residents to stay indoors was deployed. However, the sirens did not work well in the dense fog, and residents could not understand the message. Instead, the sirens awoke many residents who were sleeping (which may have been best in this situation), thereby making the situation even worse.

The local media were also not helpful in informing residents. All the area's radio stations were owned by a single corporation and housed in a single building. The Emergency Alert System and the older Emergency Broadcast System both failed, and only a single individual was running all the stations. When local officials tried to call the station on a land-based telephone, the radio operator was in a soundproof booth and did not answer the call. Officials were not able get through to the station again because frightened residents began jamming the phone lines to the station.

Additionally, the local television station, which was located in the fog, was off the air for the evening, even after officials were able to contact station representatives at their homes, they were unable to get the station and notify residents.

The derailment did not affect the community residents equally; it caused power outages to parts of the community and even destroyed some homes directly. Residents farther from the derailment had more time to react to the situation than those living close to the tracks. A multitude of variables made the situation better or worse for individuals affected by the crisis. What was common to the vast majority of the community was that they had no idea what was happening or what to do to preserve their safety.

As residents struggled to make sense of the situation, the actions one typically takes in an emergency either made the situation worse or created more questions. When residents were awakened by the emergency sirens, many of them opened their doors to see what was going on outside. This action let the dangerous chemical into their homes. When they turned on the television, it was off the air. When they turned on the radio, normal programming was playing like nothing was out of the ordinary. While this is what individuals who had power to their homes went through, those without power faced an even scarier situation.

At every turn, the normal cosmology of residents was met with bizarre circumstances, irrational calm, lack of information, and overwhelming uncertainty. The best way residents could have reacted to the situation was to keep their doors shut, turn off their furnace (the temperature was below zero), go into the bathroom, place a wet towel under the door, turn on the shower, and shelter in place; however, without official information, these actions were not within the reasoning faculties of a terrified community. As a result, many residents had a cosmology episode and tried to flee the situation.

Many residents were able to drive their cars out of town through the less dense areas of fog. However, others became trapped in their vehicles as the fog disabled vehicle engines. Others became disoriented, could not find the road again, and crashed into things such as their neighbor's house. Others tried to find better shelter and tried to run to a neighbor's house. As a result, many residents were seriously injured, and one resident died.

Coupling

Crises do not emerge out of the blue. More often than not, in retrospect, we are able to acknowledge a series of events that led a specific crisis to happen. Exogenous and endogenous factors are usually combined in the enactment and development of social crises. Although some crises might be produced by a single technological malfunction, a natural disaster, a human mistake, or a planned misconduct, other crises can be the result of all these factors combined in unexpected and hazardous ways. It is important to note that the effects produced by a crisis cannot be reduced to the elements that compose it.

To understand how a social crisis is produced and to find ways to manage it effectively, it is important to identify the elements involved in the crisis and the ways in which these elements are linked to each other. The components that take part in a crisis may be human in nature (e.g., individuals, groups, organizations, or larger communities) or nonhuman (e.g., technological devices or environmental conditions). The ways in which the constitutive elements of any given crisis are "coupled" will largely determine the crisis's nature and scale of impact.

Let us propose an example. Multiple factors were involved in the loss of the space shuttle *Challenger* in 1986. The incident was instantly captured by the media. A few seconds after the *Challenger* was launched, thousands of eager spectators were able to see the smoke trail left by the disintegrated spacecraft and, with it, the vanishing of hopes built around this nationwide project. How did this happen? How is it possible for such a catastrophic event not to be anticipated, even by experts? Mixed signals provided by environmental conditions, technological failures, political pressures, and organizational mistakes led the highly trained engineers and scientists at the National Aeronautics and Space Administration (NASA) to make a wrong decision that, in this case, led to fatal consequences. Probably, none of these factors, by itself, was particularly harmful; it was the combination, or "coupling," between all of them that led to a disastrous outcome of incalculable qualitative and quantitative losses. This example shows that the higher the number of components involved in a disaster, the higher the level of complexity of the disaster and the more difficult it is to identify a single factor as responsible for its occurrence.

In addition, the kinds of couplings, or "linkages," between the components involved in a crisis play a crucial role in determining the nature and scale of its effects. We distinguish here two types of couplings: loose or tight couplings. The term *loosely coupled* is commonly used to describe complex assemblages whose components are only weakly connected; that is, they interact in diverse ways and are capable of more autonomous actions. A research consortium that lacks a legitimate authority and that promotes an equal participation among its members could be seen as an example of a "loosely coupled" arrangement or organization. The fact that this kind of organization does not stipulate a unique way of functioning might give rise to a higher fluidity of ideas, with more flexibility to test and improve those ideas and possibly open higher opportunities to make mistakes, than would be encouraged under a highly strict form of organization. The term *tight coupling*, in contrast, refers to highly interconnected parts in which the malfunctioning of some parts may lead to major crises or disasters. An army organized in a highly hierarchical form, for instance, could be seen as an example of a tightly coupled organization, in which slight changes (e.g., failure to convey or obey a command) might have strong repercussions in the system as a whole. In this kind of organization, we can imagine a superior saying to his subordinate: "Here, there is only one way of doing things." Any deviation from the formal line of command may give rise to mistakes or disasters of incalculable dimensions that can put at risk the well-being of all organizational members, especially under situations of high pressure.

These examples suggest that failures may be more difficult to manage when the interacting components of a crisis become more and more interdependent. This could happen because the opportunities to find solutions for any given problem become more and more restricted. In other words, the group, organization, or community that is being affected by the crisis becomes less capable to react and to respond to adversity in more flexible and creative ways. An insightful study of the case of the *Challenger* launch decision discussed above found that the systematic condensation of information within NASA allowed highly complex evidence to become more and more manageable, yet at the same time obscuring conflicting elements that were critical in evaluating the launch of the spacecraft. Therefore, while summarizing the data available allowed the group at NASA to make a decision, it did so at the expense of masking important pieces of information that could have radically changed the course of the decision making as well as the after-effects.

In summary, to effectively assess, analyze, manage, and resolve crises, we need to take into account not only the factors involved in the crisis but also the interactions between these factors; irrespective of crises being large or small, expected or unexpected, or organizational, business, community, or political. Both the constitutive components and the relationship between these components play a crucial role in shaping a social crisis and its impact. On one hand, the concept of "coupling" reminds us that the interconnections between the elements of a crisis matter when examining the nature and possible causes of crises as well as when trying to find solutions to crises. On the other hand, the notions of "tight and loose coupling" invite us to turn our attention to the types of interconnections between the elements that take part in a crisis, that is, the level of interdependency between these elements and the opportunities that they may open to make failures more or less likely to happen or more or less difficult to deal with. Crises do not emerge out of the blue. When analyzed in retrospect, we can usually identify a series of minor mistakes that were catastrophic in combination or perhaps an impossible-to-predict incident that happened just in the wrong moment.

Credibility

Credibility refers to the trustworthiness and believability of a source or message. Classifications of credibility are different among disciplines and types. Credibility is constructed of many smaller interpretations such as integrity, likability, reputation, reliability, accuracy, consistency, authenticity, plausibility, and honesty. In other words, credibility often ebbs and flows based on perspective. A person, organization, message, or datum is fully credible when it has predictive value. Thus, full credibility is linked to the predictability of honest correctness, which is especially important during crises. Organizations or individuals that are not perceived to be truthful may have their messages rejected by the publics they are attempting to reach.

Types of Credibility

Statistical and scientific credibility refer to the extent to which a researcher can rely on a data set. Whereas statistical integrity denotes trustworthy and valid numerical data, scientific credibility refers to the reliability of rigorous research and data outcomes. In scholarly circles, one way to accomplish this level of credibility is by submitting work to undergo the peer-review process, in which other experts read, critique, and sanction method application and findings.

Source credibility refers to the believability of a speaker or communicative source (e.g., newspaper, network news, radio program, magazine, scholarly article, etc.). Aristotle claimed that effective persuaders appeal to audiences through logic (logos), ethics (ethos), and emotion (pathos). An ethical appeal is possible only if the source and message possess character and goodness (i.e., credibility). A source is credible when perceived as competent and demonstrating character. Source credibility is commonly conceptualized as honest expertise, which entails extensive subject knowledge and trustworthiness. There are endless varieties of source credibility, including media credibility, newspaper credibility, supervisor credibility, corporate credibility, brand credibility, and spokesperson credibility.

Experts in public speaking and persuasion detail three kinds of credibility that speakers and organizations can attain: initial, derived, and terminal credibility. Initial credibility is the authority or trustworthiness ascribed to a speaker before he or she delivers a message. Initial credibility is connected with a person's educational success, career achievements, organizational reputation, professional attire, preparation, visual and nonverbal cues, and any other information an audience perceives before the speaker begins. Derived credibility denotes the level of believability a speaker maintains or earns throughout the message-sharing process. The degree to which a speaker provides a lasting impression of integrity and competence is known as terminal credibility. Terminal credibility is the composition of both initial and derived believability. Initial, derived, and terminal credibility are assessed by audiences or stakeholders through both subjective and objective means. Credibility is based more on subjective interpretations than objective methods, since trustworthiness is often described as a "gut feeling" or "sense." Some amount of credibility is assessed objectively, like speaker certifications or facts and messages that align with the listener's confirmed knowledge.

Building Credibility

Credibility is created among audiences, communities, and stakeholders through evidence and persuasive tactics. First, evidence bolsters credibility through the use of supporting materials. Providing logical support for an argument adds to a speaker's expertise. Similarly, personal experience also provides credibility because real-life involvements enhance a speaker's perceived authenticity. Second, speakers who formally establish credibility through the introduction of their title, degree, expertise, or life experience derive believability from audience members. For example, the Centers for Disease Control and Prevention (CDC) often invites high-ranking experts and officials at their agency to speak at press conferences. Prestigious titles and scientific knowledge enhance a speaker's credibility and, therefore, a message's believability. Finally, timely charisma and passion influence audience perceptions of trustworthiness. Speakers who demonstrate excitement and conviction for their topic seem credible to listeners. Martin Luther King, Jr. (MLK), for instance, was famous for his passionate public speeches during the civil rights movement. MLK's speaking dynamism added to his credibility, the effectiveness of his message, and possibly the revolution of racial integration across America.

Alarmingly, numerous studies have correlated physical attractiveness and likability with credibility. This means that spokesperson appearance can play a role in audience perceptions of message believability. Engaging speakers appear sincere, and attractive speakers appear truthful, thus earning audience perceptions of competence and character. This phenomenon accounts for why many companies hire winsome spokespersons and beautiful models as product endorsers. Arguably, the intentional use of attractive speakers in crisis response situations could be considered unethical, as it would mean an organization is relying on perceived attractiveness for credibility rather than on the truthfulness of the message.

Credibility and Crises

Trustworthiness is key for effective communication and crisis management since noncredible messages are disregarded by stakeholders and publics. Crisis communicators must strive to be credible spokespersons before, during, and after a crisis event. If an organization has a questionable reputation before a disaster, the company's crisis response messages will be dubious. However, pristine reputations enhance an organization's credibility during the crisis management process. Credibility contributes to effective crisis communication and, therefore, can operate as an antecedent indicator of crisis resolution. In other words, responsible organizations must strive for transparency and authenticity—attainable through open and honest crisis communication. The National Center for Food Protection and Defense (NCFPD), a Department of Homeland Security center of excellence, outlines best practices in crisis response. Many of the best practices correspond with notions of credibility, for example, (a) collaborating with credible sources, (b) communicating with compassion and concern, and (c) demonstrating honesty and openness. Effective crisis management requires speaker, message, and organizational trustworthiness. Thus, credibility is paramount in the pre-crisis, crisis, and post-crisis phases.

Crisis, Definition of

Crisis may be defined in several ways, depending on the context and the field under consideration. According to the Merriam-Webster online dictionary, a crisis is a crucial and unstable state of affairs with a possibility to bring about a decisive change. In a more general sense, a crisis is mostly an abrupt and unexpected negative change creating a critical, dangerous, and unstable situation at the individual, group, organization, or community level.

Crises are often characterized by disruption of normality and steadiness of processes, thus creating chaos of various degrees. Most of the time, crises emerge suddenly; however, they can also be in the form of a long process requiring long-term solutions. Because crises have the potential to create a chaotic environment, they tend to limit skills and capacities present in noncrisis and routine situations. Accordingly, as Matthew Seeger, Timothy Sellnow, and Robert Ulmer state, because crises are unexpected and nonroutine events, they first of all result in uncertainty. Uncertainty, in turn, is a situation with unprecedented characteristics that make it difficult to resolve the crisis immediately. In most general terms, uncertainty is when actors involved in crisis cannot appeal to a certain solution tool due to lack of sufficient decision-making capacity.

Decision-making capacity itself is dependent on several factors, one of which is time pressure. Actors involved in crises are mostly bounded by limited time for resolution, because delayed solution may bring about a deepened or permanent crisis situation. In addition, crises impact decision-making capacity in terms of information required to make high-quality decisions. In this sense, crisis actors generally have limited or no relevant information to make good decisions. Even in times of abundant information, the time pressure related to crises does not allow for detailed and long-run analysis of that information, thus making crisis actors suffice with limited information at hand. For this specific reason, crisis situations are also characterized by heightened risk—a possible failure to make well-informed and satisfactory decisions. In this regard, actors involved in crisis may face unexpected or unintended results that may be consequential in determining the failure or the success of the crisis resolution process.

The risk is also evident in inability to retain or requirement to change the previous situation if the crisis is to be managed successfully. In fact, many scholars and crisis management professionals state that crises are an opportunity to learn. Kathleen Tierney and colleagues state that from an organizational point of view, crises are a chance to find mistakes in the system, fix them, develop redundancies for backup purposes, and strengthen the capacity against future crises. This view about crisis is similar to the description of crisis in an edited book by Arjen Boin and colleagues, according to which crisis serves two many purposes if seen as an opportunity. First, it tests the resiliency of the system, society, etc., namely, how strong it is against unexpected problems and unintended flaws. Second, it tests leadership capabilities of those very structures or systems, thus presenting an opportunity for political change.

By this token, crises can be seen as an opportunities for change. Change is deemed necessary because crisis is seen as a result of some sort of incompatibility that cannot be prolonged anymore. The word *crisis* in the Chinese language is expressed by two hieroglyphs standing side by side, the first meaning "danger" and the second meaning "opportunity." Thus, crises should not be always seen as problematic cases; rather, actors involved in crisis should direct their efforts toward elimination of incompatibilities and flaws in systems, structures, or relationships.

Although crises can be of an interpersonal nature, they can also be at the organizational, community, or international levels. The best-known types of crises are those related to economy, demography, environment, security, and natural and human-made disasters. A global food crisis and a diplomatic crisis between two states are two different examples of crises. Without doubt, such variety of crises requires different crisis management tools, skills, and capabilities that are nontraditional and nonroutine in nature. The scope and nature of crises are the main determinants of the crisis management approach.

Depending on the field or discipline, the word *crisis* may be used interchangeably with the word *emergency* or *disaster*, where the former is more general and the latter is more specific. Whatever the term, the main idea is that there is an anomaly to be fixed. Successful crisis, emergency, or disaster management, thus, is characterized by reestablishment of previous normality, whether through change or without change.

Crisis Communications

Crisis communication is a process, not just communicating a single message, to a single group, or at one point in time, and as T. E. Drabek points out, it is very much a social process. It is interactive and consists of multiple messages extending often over very long periods of time and changing conditions, and designed for many different groups (by language, age, and other demographic characteristics), places, and decisions or actions. The process needs the support of management—crisis management—across its many stages from prevention through response and recovery. Management and communication frameworks in noncrisis environments are an important and integral foundation for communicating when a crisis emerges. Crisis communication has to begin before a crisis occurs.

A central goal of crisis communication is to reduce risk through individual, group, or institutional action. Decisions or actions are usually a prerequisite to identifying and implementing communication strategies. Some specific communication objectives in catastrophes include the following:

- Reducing exposure to the risks through timely, accurate, and appropriately disseminated or targeted information
- Guiding people in the high risk/exposure areas to safe places
- Keeping people away from entering the area
- Adopting and implementing protective action such as vaccines, shelters, etc.
- Connecting supplies and services with the people who need them
- Reducing fear and anxiety

Communications are influenced by crisis characteristics and human factors. Communication is shaped by characteristics of crises that include urgent action and decision making in a highly uncertain and complex environment created by constantly changing or dynamic information, and variations in effects from place to place and individual to individual, even for the same crisis. These multidimensional needs require coordination that ultimately expresses itself in communication. Human perceptions, attitudes and behavior, and human settlement patterns and trends influence receptivity to communication and how people respond in disasters as a guide to risk reduction and protection of life, welfare, and property.

Cases of successful and unsuccessful crisis communication are first presented to illustrate how timing, accuracy, and capacity to communicate influence outcomes, followed by foundations of communication in human perceptions, attitudes and behavior, and human settlement patterns and trends, and finally, communication strategies based on lessons learned and theories of human behavior.

Perception, Attitudes, and Behavior

Many fields such as social psychology and risk management address how communication motivates and influences human behavior in crises. The common sender-message-receiver model now incorporates behavioral dimensions such as the M. Lindell and R. Perry Protective Action Decision Model (PADM). The perception-attitude-behavior relationship is complicated by the lack of correspondence between people's beliefs or what people say they would do and their actual behavior. Certain behavioral tendencies and barriers to processing information have been identified. People process communications and the information they contain in many different ways, using as a guide their experience, information from other people, their senses, and their ability to recognize patterns. Examples from theory are given below.

B. Fischhoff, P. Slovic, S. Lichtenstein, S. Read, and B. Combs emphasize that people accept risks that they personally control (such as driving a car rather than air travel) undertake voluntarily, and consider familiar and common, chronic or ongoing (not immediate and nonfatal). They accept risks that they or science know with certainty.

Information expressed as numbers can be problematic for some people, and Peters and colleagues describe the numeracy concept as understanding numbers. Numeracy is related to other problems that affect action. People have limitations on the amount of information they can process and can become overwhelmed by negative stimuli. Slovic's research (2010) refers to this as "psychophysical numbing," arguing that people feel strongly about harm to an individual but cannot grasp genocide, where large numbers of people are involved; that is, they undervalue large

Case Studies in Unsuccessful Communication

In the latter part of the 20th century and the early 21st century, record levels of crises occurred worldwide from natural hazards, accidents, and terrorist attacks, testing the limits of crisis communication, as summarized by R. Zimmerman (2012) based on U.S. agency information. Timeliness, accuracy of communication, and communication capacity and capability to deliver messages to connect supplies and services with those in need are critical to reducing the adverse outcomes of crises, and selected cases below are organized according to these three areas.

Accuracy of Messages

In very sudden, unexpected, and rapidly emerging catastrophes, some with little precedent, messages were inaccurate or not given at all due in part to an inability to assess the situation given the difficulty of obtaining or understanding information.

As mentioned earlier, messages are targeted to actions or decisions. Evacuation is one common decision in crises that requires timely and accurate information—whether, when, and how it is to be done. Communications go hand in hand with those decisions. Some cases that illustrate communication accuracy in evacuations are summarized below.

In the Tohoku earthquake in Japan on March 11, 2011, the Fukushima nuclear power plant failures were associated with messages as to where people should evacuate. N. Onishi and M. Fackler indicate that people were told to evacuate to the north, since winds were blowing to the south, when, in fact, information that these people didn't have showed winds blowing to the north, resulting in people relocating to contaminated areas.

In the 9/11 terrorist attacks, the 9/11 National Commission identified messages from some designated safety officials that New York building occupants should stay in their offices or move away from fires, a type of shelter-in-place strategy used in some emergencies but not where a total building collapse is expected to occur, a condition that was either not known or not expected at the time.

In the L'Aquila earthquake of 2009 in Italy, H. Fountain's review points out that people were told by some officials that it was safe to stay where they were; several hundred people perished.

Timing of Messages

Delay in the delivery of messages can potentially vastly increase casualties and other impacts.

In the Virginia Tech sniper shootings of April 16, 2007, as reported by Reuters, a fine was issued under the Clery Act [Jeanne Clery Disclosure of Campus Security Policy and Campus Crime Statistics Act or 20 U.S.C. § 1092(f) of 1990] by the U.S. Department of Education because university officials delayed university-wide warnings of the attack for two hours as they followed a lead, resulting in 32 deaths and more injuries. Reuters reported that as of March 31, 2012, the fine was overturned. The Haiti cholera epidemic following the January 2010 Haiti earthquake was confirmed in October by the U.S. Centers for Disease Control (CDC); military missions brought in for assistance were thought to be the cause. Timely communication of epidemiologically based warning signs such as the existence and rate of emergence of the disease to enable the population to avoid further exposure did not prevent what the World Health Organization/Pan American Health Organization (WHO/PAHO) estimated as about 7,000 deaths from cholera and more than half a million (515,699) cases toward late 2011. A major obstacle to communicating its existence and extent is that, according to the WHO/PAHO and the CDC, most of the infected people do not exhibit symptoms.

Communication Capacity for Supplies and Services

Communication capacity within and among agencies and with the public connects supplies and services to people in emergencies. The ability to communicate effectively with suppliers to match supplies with need is a major challenge. When abundant supplies are provided but are not what is needed, the imbalance becomes a disposal problem. The ability to control voluntary contributions, for example, is a major management problem.

The New York City snowstorm of December 26, 2010, was an unusual blizzard, characterized

(Continued)

(Continued)

by the National Oceanic and Atmospheric Administration (NOAA) as the sixth-largest (in Central Park) since the 19th century. As summarized in part by Zimmerman (2012), the New York City Council hearing January 10, 2011, New York City's report by Elizabeth Weinstein and Skip Funk, and the MTA Office of the Inspector General reported deficiencies in communication with respect to the inability to declare a state of emergency, the inability of snow removal vehicles to communicate with one another due to insufficient equipment, overloading of existing communication channels, the absence of geographic information system (GIS) equipment to locate and deploy the vehicles, and the inability to communicate with workers to enable them to get to the vehicles. According to the MTA Inspector General's report, deficient public transit system communication systems and operational procedures also contributed to continued deployment of transit vehicles during the storm that were immobilized, stranding passengers; these communication deficiencies included problems with internal communications linking bus operators, dispatchers and road response units for vehicle tracking and response to disabled vehicles external communications with passengers that were delayed, inconsistent, or incorrect; and communication equipment failures. Ultimately, New York City increased the availability of communication equipment and made other organizational and procurement changes. As Zimmerman (2012) concludes, the city had other chances to improve these conditions with other snowstorms that followed in January 2011 and the extensive evacuations in connection with Hurricane Irene.

According to a 2011 National Research Council report, the December 2004 Asian earthquake and tsunami that killed more than 200,000 people revealed deficiencies in the notification of the onset of the tsunami and led to the development of an extensive tsunami warning center structure.

Based on accounts from Todd Litman and others, Hurricane Katrina of 2005 exemplified the failure of communicating to people where they could obtain supplies and services both before and after the hurricane; in some hospitals, people were told to wait for emergency personnel to help them leave, yet none arrived; and people who made it to shelters found it difficult to communicate with suppliers.

numbers. He uses a survey to argue this in which the more people affected, the lower the dollars per capita were granted to support them. In this context, he also brings in the concept of affect or quick feelings and that people cannot grasp numbers emotionally.

Slovic, Fischhoff and Lichtenstein, and A. Tversky and D. Kahneman identify some of the biases in the way people process information: for example, underestimating large risks and overestimating small ones, called "availability." In earlier works, Tversky and Kahneman as well as Slovic, Fischhoff, and Lichtenstein identify "anchoring," or the influence of previously held values on current beliefs. Education may not always overcome these beliefs. Prior experiences also can influence people's attitudes toward risk and defensive actions they are willing to take to reduce risk, as E. Lichtenberg and Zimmerman showed in the context of farmer behavior toward the risks of pesticides.

Individual, group, and cultural characteristics such as age, gender, race, ethnicity, and income have been related to variations in risk perceptions, for example, traced by J. Flynn and colleagues in a 1994 paper for numerous threats.

According to social psychologists, biases also occur in people's ability or willingness to adopt protective action (evacuation to prevent injury and loss of life, insurance to reduce property losses) before, during, or after a catastrophe.

A number of other human behavioral concepts are directly significant to communication. "Mental models" are a composite of people's knowledge, experiences, and preferences that they bring to new situations, and can change over time, as M. Morgan, B. Fischhoff, and A. Bostrom have explored. The concept of "social amplification" set forth by R. Kasperson and colleagues emphasizes that risk experiences and heightened perceptions of risk are shaped by perceptions, technical details of events, and information, and are understood when all of these factors are integrated or conceptualized in the same context.

In crises, people tend to seek information and other people for information and support. The R. Zimmerman and M. Sherman study of 9/11 survivors in New York City reported that half of the people leaving Towers 1 and 2 lingered to seek information and people, and the other half left immediately. Other studies have shown that people have certain predilections toward whom they seek information from. Trust is one of the strongest factors that relate to beliefs about risks, as Slovic has shown, and whom people are likely to listen to. People tend to obtain information from their peers and use sources with which they are familiar.

What, How, and When to Communicate

The study of communications, especially as warnings, encompasses when and how to warn. One important aspect of when to warn is the identification and communication of precursors. J. Phimister, V. Bier, and H. Kunreuther identify accidents in which the causes were known but not acted on. Hindsight takes over after a catastrophe, and precursors abound in many different ways. In catastrophic earthquakes, precursors are often evident in the form of historical trends in earthquakes in an area. According to the National Oceanic and Atmospheric Administration (NOAA) and the U.S. Geological Survey (USGS), prior to the March 11, 2011, Japan earthquake, Japan's location in a high earthquake-prone area, the "ring of fire," was well known, and earthquakes were registered near that date. T. Litman describes how New Orleans was forewarned of the dangers in a community dependent on transit. The question remains as to whether communicating prior trends makes it easier to communicate a need for risk-avoidant behavior, in the form of relocation, preparedness, and so forth, that people would act on.

Government agencies, to simplify hazard communications, rely on common integer or logarithmic scales, usually with under a dozen categories, accompanied by a verbal description of expected damages for each category. Examples are the USGS's use of the Richter and Mercalli Intensity Scales for earthquakes, the Volcano Explosivity Index, the Sieberg Tsunami Intensity Scale and NOAA's Saffir-Simpson Hurricane Wind Scale,

Case Studies in Successful Communication

In Japan's Tohoku earthquake of March 11, 2011, NY1 newsreporter Dean Meminger reported that some school children were saved by having experienced emergency drill procedures, though in other cases, emergency warning exercises can lead people to ignore them.

A report by the U.S. Department of Transportation's Volpe Center, headed by project manager Allan J. DeBlasio, describes the rapid response of transit systems after the 9/11 attacks in New York City. They describe how a train operator becoming aware of the impact communicated to others within a minute, resulting in the commencement of emergency procedures. The Port Authority Trans-Hudson (PATH) system acted similarly; within a half hour, shutdowns of roadways and airports followed, and within two hours a system-wide shutdown of subways and the PATH occurred.

Researcher Rae Zimmerman summarized how utilities, during response and recovery to 9/11 attacks in New York City, were able to tap a vast network throughout the United States to obtain and install electrical generators, distribution lines, and cell towers to temporarily restore electric power and communications, and the communication network to do that predated the outage.

Prior to Hurricane Irene's landfall in Brooklyn, New York City, on August 28, 2011, a record pre-event nonmandatory evacuation occurred of close to 2 million people in the New Jersey and New York portions of the New York region alone. The evacuation required timely, accurate, and well-organized communications about the threat's validity, locations of highest vulnerability based on hazard mapping and analysis, and where people could go. The messages were delivered at the highest levels of government with considerable seriousness, with follow-through by emergency response organizations.

In the Indian Ocean tsunami on December 26, 2004, the National Oceanic and Atmospheric Administration recounted stories of how training enabled people to get to safety and how a tribe read the signs of receding waters as a tsunami, thus enabling them to move to higher ground.

the Enhanced Fujita Tornado Scale, and various precipitation, drought, and heat indexes. The U.S. Department of Homeland Security replaced its five-part scale in 2011 with the National Terrorism Advisory System, which provides detailed information on a threat, including whether it is elevated or imminent. Agencies and organizations managing critical infrastructures routinely use aggregated hazard, condition, and performance measures to signal vulnerability and threats. These scales simplify communication; however, the mathematical formulations do not easily map to specific situations, locations, and time periods. Another aspect of how communication is accomplished is communication technology. The very rapid growth of alternative communication methods and the differential transfer to individuals makes this a difficult question to answer. One important lesson is that most communication technologies depend on electric power, which is often disabled in a crisis.

Guidance for the design of crisis communications emerges from a very large literature. It includes, for example, the U.S. Environmental Protection Agency's risk communication "rules" to involve audiences actively in the process, gain trust before communication occurs, respect and be compassionate about audience concerns, and rely on accurate information. Other guidance addresses presentation style, emphasizing the use of graphics, where to place key messages, and the use of trusted messengers.

Conclusion

Crisis communication is an old field of study but will continue to face new challenges as crises change form and intensify and the structure of social networks and who is trusted changes. Fundamentally, effective communication, defined as keeping people safe from harm, depends on trust and individual willingness to adapt behavior to what is being communicated. Communication is an interactive, ongoing process engaging senders and recipients and, though the combination of individuals is usually unique to each situation, modes of communication have emerged that situations share in common.

Crisis Information Management Systems

Crisis information management systems (CIMS) are employed within emergency operations centers (EOCs) to better coordinate complex emergency response and recovery efforts. An EOC provides a physical location for the centralized management of emergency operations, including the collection, management, and documentation of information. CIMS were developed to aid in this process. Information technology (IT) was targeted as essential to improved emergency response and recovery coordination. Crisis information management software, also known by the acronym CIMS, is an essential component of many crisis information management systems. CIMS usage provides improved efficiency, faster and more flexible emergency response and recovery times, and more fully informed decision-making capabilities, which in turn can save lives, property, and money.

Crisis information management system has become the most widely accepted term within the emergency management field. Other terms in use have included *disaster management interoperability system*, *coordinated incident management system*, and *critical incident management system*. Emergency response and recovery usually requires multiple agencies at various levels of government and/or between government and the private sector. CIMS provide more effective central command and control operations within EOCs, alleviating problems such as redundancy, confusion, miscommunication or lack of communication, and delays.

Development and Use

The development of CIMS in the United States was part of a larger effort to improve emergency response and recovery efforts under the Department of Homeland Security and the National Incident Management System. These efforts occurred in the wake of systemic problems identified after the 9/11 terrorist attacks in 2001 and Hurricane Katrina in 2005. Critical among these problems was a general lack of overall situational awareness among the many agencies dealing with disasters, pandemics, or terrorist attacks. National government agencies and areas with large populations have been among the first to adopt CIMS.

CIMS are not used only in federal, state, and local government EOCs. Private-sector use spans diverse industries such as telecommunications, utilities, energy, security, health care, agriculture, banking, and education as well as various voluntary and nonprofit agencies. Other countries as well as international nongovernmental organizations (NGOs) have implemented CIMS. The United Nations (UN) has worked with the ICT4Peace Foundation to develop a CIMS as part of its UN Crisis Information Management Strategy. The goal is to better coordinate international humanitarian disaster and conflict response and relief efforts in response to problems identified through the 2010 Haiti earthquake, among other disasters.

Although there are no standard requirements for CIMS, many CIMS share common components. Operational methodology management identifies and defines the core concepts underlying the EOC's mission, while the incident management or command system outlines the command-and-control structure as well as relations among the various agencies and government levels involved in emergency operations. Situational awareness utilizes the information gathered through CIMS to allow EOC personnel to be fully informed of the current crisis as it unfolds in real time. CIMS may also encompass daily EOC management and planning and preparedness activities.

Personnel management covers defining individual, team, and organizational roles and duties as well as mission and source tasking. Notification management covers incoming and outgoing messages such as assistance requests, press releases, and public alerts. Document management ensures that all documents either collected or produced by CIMS are properly stored and easily retrievable, while report management allows for the generation of status and other vital reports. Notification and document management also ensure reliable communication as well as access control such as user authentication and authorization services and data security. Financial management encompasses effective tracking and utilization of assets,

Centers for Disease Control and Prevention (CDC) acting director Richard Besser shows U.S. Secretary of Health and Human Services Kathleen Sebelius logistical assessments relating to swine flu outbreaks posted inside the CDC's emergency operations center on May 5, 2009, in Atlanta, Georgia. The CDC uses WebEOC, an Internet-based, locally configurable incident and event management tool.

resources, expenditures, budgets, and assessment modeling such as damage assessments. Other management tasks can include shelters, mobile recovery sites, and infrastructure such as roads and bridges.

Software

CIMS software is a critical component of CIMS. These software programs are designed to provide the communications and information technology support critical to the EOC's functioning. CIMS software can perform a variety of functions such as alert network operation and notifications, event evaluation, task assignments and prioritization, resource deployment, briefings, and real-time monitoring. CIMS software can even be designed to function as a virtual EOC. CIMS software may be designed as stand-alone but generally does not operate in isolation. There are both Web-based and non-Web-based CIM software programs.

The local autonomy granted by the U.S. federal government has led to the creation of a variety of CIMS software products and allows various EOCs greater flexibility in deciding which CIMS software to purchase. Companies that offer EOC CIMS software include Alert Technology (makers of Ops Center), Blue292, Emergency Manager (makers of the product of the same name), Emergency Services Integrators or ESi (makers of WebEOC), E-team, Essential Technologies (makers of Incident Master), *Soft*Risk, Ship Analytics (makers of L-3 CRISIS), Public Safety Group (makers of EM/2000), and Strohl Systems (makers of Incident Manager). The U.S. Department of Homeland Security manages its own secure Web-based information-sharing portal known as the Homeland Security Information Network (HSIN).

The various CIMS software products contain many of the same components, such as emergency support functions; command, control, and communication functions; and resource management functions. Specific components often include weather and plume modeling, street mapping, geographic information systems (GIS), and monitoring and data acquisition systems such as aerial and satellite photography, cameras and closed-circuit television, and CBRN sensors. Most CIM software utilizes databases for data storage and sharing capabilities. The most common data transfer method is the Internet Protocol (IP), and the most common data exchange language is eXtensible Markup Language (XML).

The National Incident Management System Supporting Technology Evaluation Program (NIMS STEP), established by the Department of Homeland Security in 2005, evaluates CIM software as part of its duties. Several key studies have also evaluated CIMS software programs across vendors to identify benefits, problems, and user needs. These include the National Institute of Justice's 2001 "Crisis Information Management Software (CIMS) Feature Comparison Report," the Institute for Security Technology Studies' 2004 "Crisis Information Management Software (CIMS) Interoperability: A Status Report," and 2007 and 2008 surveys conducted by the U.S. Air Force and the University of Colorado Center for Homeland Security.

One of the key concerns identified in comparisons of CIMS and CIMS software is the issue of interoperability, or the ability of separate systems and software programs to communicate critical information and exchange services. Interoperability is essential to proper functioning between various EOCs as well as between EOCs and their users. CIMS must also be designed to operate effectively between multiple agencies and responders within the government and private sectors. CIMS must also adapt to the varying levels of infrastructure, information technology knowledge and accessibility, and information technology systems these agencies may possess.

CIMS and CIMS software are flexibly designed to allow for adaptation to location, agency, or type of emergency. CIMS must also account for problems that often arise during emergencies, such as network outages and damage to communications or information technology infrastructure. The most effective CIMS are easy to use and implement in an emergency; work in challenging environments and conditions; do not require extensive training, maintenance, or support; can be customized to suit specific needs; and are interoperable with other CIMS and emergency management systems. CIMS are ultimately reliant on their underlying structures, software, and personnel for success.

Common terminologies, responder roles, and frameworks for information flow have yet to be fully developed or widely adopted, hindering CIMS interoperability and the ability of agencies in varying fields to communicate. Other problems include the unwillingness of agencies to share data, data security and access issues, the use of sector-specific standards, and redundancy across agencies and sectors. Future challenges are to improve interoperability and standardization of use and to overcome resistance or boundaries to CIMS use, including data security, cultural, and financial issues.

The OASIS consortium is one of the leaders in the development of universal CIMS standards through its Emergency Management Technical Committee. The first was their 2005 Common Alerting Protocol (CAP), which provided a common XML format for use in alerting and public warning systems. CAP users in the United States include the Department of Homeland Security and the National Weather Service. Other standards in practice or under development (as of 2012) include the Emergency Data Exchange Language (EDXL), which itself includes the EXDL Distribution Element; the EDXL Resource Messaging; and the EDXL Hospital Availability Exchange Language.

Crisis Management, Emerging Trends in

A crisis is a significant issue affecting a firm or its stakeholders that, if left unattended, can lead to severely negative outcomes. Key characteristics of a crisis are that it requires an immediate response, has low probability of occurrence but high impact, and is clouded in ambiguity of cause, effect, and resolution. As the number and frequency of crisis events have grown in recent decades, the sophistication of crisis management responses has also matured. Below are three emerging trends that are worth attention if organizations want to continue to develop their crisis management capability.

Emerging Trend: Bridging the Cultural Divide

In its most comprehensive form, crisis management is marked by five primary activities: signal detection, preparation and prevention, containment and damage control, business recovery, and learning. By and large, however, it is the crisis containment and damage control activities that receive the lion's share of attention by organizations in crisis, by those responsible for managing the crisis, and by victims of a crisis. Damage control is marked by two types of behaviors. The first is crisis containment, where the focus is on immediate problem resolution. The goal of crisis containment is to limit the reputational, financial, and other threats to firm survival. This can be achieved by activities that limit the encroachment of a localized crisis into otherwise unaffected parts of the organization or the environment. In BP's case, there was an urgent need to stop the spread of oil along the shoreline. One of the firm's technical responses was to deploy booms that would contain the oil.

Beyond the technical response to crisis management and containment, however, is the communication response. It is through an effective communication and public relations strategy that a company is able to convey to stakeholders the severity of the crisis, instructions (e.g., in the case of an emergency that might require evacuation procedures), plans for resolving the crisis, and more. It is also through the communication channels that a company can frame the cause and accountability for the crisis, convey remorse, and attempt to connect with victims. Of course, different types of crisis require different types of responses, and there are numerous crisis typologies to guide firms in knowing which type of response is appropriate in any given situation.

Using the example of the BP Gulf oil spill, we see a growing need for companies that operate around the globe to manage crises in a way that is perceived to be culturally sensitive to stakeholders who reside in different regions of the world. In other words, the effectiveness of a crisis management response will be increasingly dependent on the firm's ability to match the crisis response to the cultural values and expectations of the victims, particularly when victims operate in a different cultural context from the firm responsible for the crisis. Using a prominent theory of national culture, there are several cultural variables firms must consider in their crisis management response, including the need to reduce the amount of uncertainty surrounding the crisis and its resolution. Crises, by their very nature, evoke ambiguity. When a firm's response fails to convey information that helps clarify the situation for victims, particularly for victims in a cultural context where uncertainty is not easily tolerated, then the receptivity of the crisis response by those victims will be low. Likewise, how one's culture values time will likely affect stakeholder reactions to crisis management attempts. Crises require an immediate response, yet a complete resolution to a crisis may take months or years. For cultures that value a short-term time orientation, they will likely respond more positively to crisis management attempts geared to short-term crisis resolution, or those actions that will have an immediate positive impact on stakeholders, relative to crisis management strategies that emphasize a long-term approach to crisis resolution. Finally, cultures can be identified according to their value for an individualistic or collectivistic orientation. A value for individualism might suggest that crisis management strategies that meet the needs of specific stakeholders (an individual and his or her family) would be more highly valued than the crisis management strategies that speak more to addressing the concerns of a broader community. Conversely, stakeholders who value a collectivist orientation will respond more favorably to crisis management attempts that seek to redress the group of victims rather than meeting individual needs.

Emerging Trend: Managing Social Media

Beyond the cultural implications of the BP oil spill crisis, the case exemplifies another growing trend in crisis management—the need to manage social media. The emergence of social media has grown out of the capability to provide access to news and information over an extended period of time. It was another oil spill, in 1989, that helped spawn the 24-hour news cycle. With word of an oil tanker (*ExxonValdez*) hitting the Bligh Reef in Alaska and spewing thousands of barrels of oil into Alaskan waters, the American news network CNN, in its infancy at the time, had a story that could be broadcast 24 hours a day, seven days a week. Back then, Exxon executives used what we now refer to as mainstream media as the primary vehicle for communicating with stakeholders. Press conferences and daily debriefing sheets were used to disseminate information locally in Alaska, and newspapers and television news networks provided information about the status of the spill to those outside the local community.

Fast forward almost three decades, though, and we see that in the BP case, social media, including Twitter and Facebook, allowed stakeholders and onlookers an opportunity to vocalize opinions and speculate about the ongoings of the crisis. Oftentimes, this public and fast-spreading speculation paints a negative picture of the focal organization, therefore requiring it to respond equally as fast with information that counters the disparaging picture of the firm. Failure to use social media to preserve the firm's reputation in response to a crisis event can put the firm at a severe disadvantage as others are able to put forth a barrage of information and speculation. Until recently, firms that have a communications department whose responsibility it is to provide the messaging around a crisis have operated through traditional or mainstream media formats, perhaps holding town hall meetings with internal stakeholders (e.g., employees) or using television interviews and newspaper ads or editorials to communicate with external stakeholders. But the time lag between traditional media relative to the instantaneous nature of social media is simply too great. With the technology available today, firms that manage messaging well in a crisis have learned to take advantage of multiple communication channels, including social media.

The growing significance of social media in industry is highlighted in the 2012 Makovsky Wall Street Reputation Study conducted by Echo Research. The researchers interviewed 150 Wall

Case Study: Crisis Management During the 2010 Deepwater Horizon Oil Spill

The summer of 2010 proved to be a troubling year for the oil giant British Petroleum (BP). The Deepwater Horizon offshore oil drilling unit in the Gulf of Mexico exploded, killing nine workers and injuring numerous others. The immediate aftermath of this crisis was significant, but the longer-term consequences were even more severe for BP and for a host of stakeholders affected by the ongoing oil leak into the Gulf waters. The leak lasted for a period of months. Local communities whose livelihoods depended on a symbiotic relationship between the oil and gas industry and the tourism industry were paralyzed as BP and the federal government worked to stop the leak from decimating the supply of seafood and the environment. Tainted seafood meant that the restaurant industry and local fishers and shrimpers would see revenue decline to dangerously low levels. Tainted beaches led to a drop in visitors to the coast just at the peak of the tourist season. As a result, the general economy in the Gulf states was also threatened.

To make matters worse, BP's chief executive officer (CEO) and primary spokesperson at the time, Tony Hayward, communicated publicly in ways that raised the ire of many U.S. citizens. Hayward, a British citizen, became infamous for communication and public relations blunders that suggested he was out of touch with and insensitive toward the needs of the local Gulf community. His unmistakable British accent seemed to exacerbate the frustration that a "foreign" company was seen as responsible for causing such devastation in the United States. Among Hayward's more controversial blunders was a comment in a press conference stating "I'd like my life back." The interpretation by many Americans was that the BP executive came across as arrogant and as being more concerned about himself than he was about the fate of the victims of the crisis. A series of poor word choices coupled with the difficulty Hayward and BP had connecting with American stakeholders seemed to highlight the cultural differences between the British oil company and the local southern Gulf community. As this gap widened, American receptivity to BP's crisis response began to wane, and disdain for the company grew, even after it began to make substantial progress on the technical response to the oil spill.

The case of the BP oil spill highlights several important trends in the realm of crisis management. One of these trends is the need for crisis handlers to develop and display cultural competence. As companies reach beyond their own national community and operate in regions all over the world, they need to prepare for the inevitability of a crisis on foreign soil. In the case of the BP explosion and subsequent oil leak, the British-based company's crisis affected U.S. stakeholders, thereby instigating a need to enact a crisis response consistent with the values and expectations of the American victims. Yet, the perception was that the firm's leader managed the crisis in ways that seemed inconsistent with the cultural values of the local community. As a result, there was considerable backlash by U.S. stakeholders to BP's crisis management attempts.

Street executives responsible for marketing and communications at large and mid-sized publicly traded and private firms and found that although more than half of the executives said that their company's social media efforts have had only neutral impact on managing their reputation, slightly more than 40 percent felt it had a positive impact on their company reputation. As crises represent a major threat to firm reputation, the ability for social media to convey reputation-enhancing information quickly can be a tremendous tool.

Emerging Trend: Striving for Innovation

The penultimate phase in the crisis management process is business recovery. This phase precedes learning and comes after the activities associated with damage control and containment. The goal of the business recovery phase has traditionally been to return the organization to pre-crisis status. Understandably, leaders want to be positioned to continue operations post-crisis and not be encumbered by a lingering aftermath. Yet the presumption that business will be the same post-crisis is a flawed one. Business will never be the same following a crisis. The crisis has caused both internal and external conditions to change in such a way that a recovery to the former status quo is impossible. There will be two options. Option 1 is that the firm will never fully recover from the crisis and toil in an effort to recuperate from the financial and reputational loss. Option 2 is that it will not only recover but will thrive in ways not imagined before the crisis. What determines the path a firm will take is the mind-set of the leader and the team responsible for managing the crisis.

When leaders and crisis managers have a mind-set of resilience, they are more inclined to manage the crisis in such a way that creates opportunities for positive change, including growth and innovation. Alternatively, when leaders have a mind-set of fear and threat in response to crisis, they are more inclined to be paralyzed and constrained in their thinking and decision making. The threat frame inhibits creativity and innovation, whereas the resilience frame ignites it.

Practically, then, the most effective crisis management strategies involve a number of resilience-related activities. For example, crisis managers will identify and treat the root cause of the crisis, not only the surface issues that typically have the most visibility. In the case of the BP oil spill, the focus was on the high visibility concerns such as repairing the equipment to stop the leak and cleaning the shoreline damaged by the oil. Clearly those items needed to have been attended to, but equally important are those crisis management activities that seek to understand the root cause leading up to the rig explosion and oil spill. Clearly the equipment malfunctioned, but identifying possible conditions contributing to the malfunction (e.g., safety culture, resources devoted to maintenance, communication channels between rig workers and management) may spark a learning that can lead to significant procedural changes or innovations that would go undetected in the absence of a root cause analysis.

In addition to a root cause analysis approach to crisis management, taking both a short- *and* long-term orientation can foster post-crisis reliance and innovation. Many of the opportunities from crisis are likely to materialize over a long-term orientation, yet most crisis management activities take a short-term perspective precisely because the immediate needs are so great. By focusing on crisis response needs over the long term, firms may see opportunities for research and development, human resources, and operational units within the firm to contribute to new product development, enhanced services, and alternative policies and procedures that may not have been visible by only focusing on the short-term crisis management responses.

Crisis Simulations

Simulations are synthetic representations of salient phenomena in the physical world. The development of simulations may include methodological approaches from traditional experimental psychology, ethnographic field methods, and domain-relevant scenarios. The platform for a simulation—that is, its medium of delivery—may range from analog to digital to virtual. Similarly, a given simulation may operate autonomously or with interaction from human agents. Crisis simulations are simulations that are meant to represent crisis situations and are found in operational, training, and planning contexts. While the focus of this article is on simulations for training, operational and planning uses are briefly discussed. This article reviews selected historical developments, the role of simulation in crisis management, and challenges for simulation designers.

Historical Developments

Field studies in human factors and related fields have provided rich and nuanced knowledge about individuals and teams at work in crisis environments. Likewise, controlled laboratory experiments have provided the foundation for countless contributions to understanding of the human characteristics that impact the development and use of systems, devices, and environments. Yet the latter are limited in what they can tell us about work situated in real-world settings, just as the former are limited in their support for precision and replicability. Enter the simulated task. Referred to by various names under the broad umbrella of games and simulations, realistic re-creations of applied work environments offer some of the best of both methodologies. They provide a means to temper the complexity of field research while facilitating controlled manipulation and observation of real-world tasks. Simulations also afford the opportunity to address real-world problems by testing ideas for innovative human-centered tools and techniques, which are brought back into the field for further study. Of course, simulated tasks are not meant to replace either approach to research. Indeed, they are interdisciplinary by nature. Field research is necessary to inform the development of an appropriate and realistic task environment. Likewise, the operation of the stimulus and collection of accurate and meaningful data relies on decades of fundamental laboratory-based research methods.

Role of Simulation in Crisis Management

Although research using simulated tasks may achieve many things where other methods fail, it is by no means a straightforward pursuit. This area is host to a diversity of conflicts, compromises, confounds, and complications, both practical and conceptual. Simulations can be quite costly and complex to develop, though off-the-shelf games have been adapted for both training and research in many crisis applications. The traditions of different disciplines regard games and simulations with varying degrees of credibility. Recruiting and retaining suitable participants can be challenging, especially with regard to naïve test subjects so frequently relied upon in academic research.

Much has been said already about what simulations and games can provide that other research methodologies do not. But the complexity and richness of the results they afford is matched by the complexity and cost of their conception, design, implementation, and validation.

Simulation Platforms

Operation of a simulation requires a platform upon which participants, technology, and, if desired, a training program may be placed. Different simulation platforms allow for different degrees of manipulation of key environmental variables in the crisis domain (e.g., tempo of crisis event, possible consequences, resources available, etc.). The following typology is useful in determining which platforms are best suited to manipulating various variables relevant to the crisis domain.

Drills are cognitive and physical activities that enable personnel to develop skills for use in executing procedures. They may also be used to develop knowledge about how these skills may be combined based on the unique requirements of a particular emergency.

Tabletop exercises use small-scale physical mock-ups of emergency situations, as well as a mix of decision makers, in order to enable a stronger connection between decision makers and the physical world. They are particularly useful for practicing roles and interpersonal interactions. The goal is to discuss problems in depth and develop decisions through slow-paced problem solving.

Functional exercises are real-time exercises that are based on dynamic models of the event. These exercises allow for near-continuous information about the event and the consequences of decisions to be conveyed to participants. The focus is on the practice of a specific function or a complex activity within a functional area. The consequences of the decisions to the emergency situation and the interactions with other functions and outside personnel are simulated. It should be emphasized, however, that the simulator may be a computer or, in the case of so-called Wizard of Oz exercises, a human controller. These exercises are more capable than the previous ones of inducing stress, because they are generally based on a rich (and therefore more life-like) interaction.

Full-scale exercises are meant to replicate, as closely as possible without jeopardizing safety, an actual emergency. This type of exercise is a scenario-based extension of a functional exercise to all the functions, and complex activities of an actual emergency are conducted under high levels of stress and real-time constraints with minimal simulation. Participants use actual facilities and resources, have access to realistic information, and are expected to behave as if the events were real.

The simulation platform may be installed in a variety of settings, ranging from realistic to futuristic. A mock-up version of an emergency operations center (EOC) often has key differences from an actual EOC, such as the presence of video and audio recording devices for capturing conversations and physical movements among participants, as well as tools for logging participants' interactions with the human–computer interface installed on their laptops. A high-tech EOC would utilize the range of current technologies to support sensing, communicating, and decision making. All three share some common essential features, such as clear lines of sight to larger-scale displays (e.g., digital and analog maps), capabilities for individual interaction with computer interfaces, a layout that facilitates direct person-to-person interaction, and technologies for communicating with EOC support staff.

Interaction and Instrumentation

Interaction and visualization tools allow interaction by individuals or groups with simulation. For example, they may enable graphical and voice-based communication between participating personnel and their staff, as well as tools for logging these interactions. In the context of planning, simulation systems such as HAZUS may be used to calculate reliable damage and loss scenarios during the initial response period when no field data are available. Systems for first responders and incident managers may be based on virtual reality technologies. The costs of incorporating these systems into interactive simulation-based training varies in part with the number of simultaneous users. The larger the group, the more technologically challenging and expensive the systems are. Distributed simulation systems are typically used for collaborative training.

Instrumentation enables integration and analysis of three distinct but related data streams, corresponding to (1) the internal state of the simulation, (2) interactions among participants (e.g., conversations, gestures, and focus of visual attention), and (3) interaction between participants and the simulation. Simulation state may be effectively captured by building logging capability into the simulation itself. For example, a complete record of system state may be made at each 5-second interval via transmission control protocol/internet protocol (TCP/IP) to a separate database.

Participants' conversations and gestures may be captured via digital audio/video taping, then time-coded to facilitate post-training analysis. Given the importance of visual search in supporting situation awareness, eye-tracking or related hardware and software may be used, perhaps in conjunction with tools for unobtrusive recording of participants' movements. Finally, interaction between participants and the simulation can be captured by logging keystrokes and mouse movements of participants.

Challenges for Simulation Design

Training requires a training environment, as implemented on some platform, within which trainees can communicate and make decisions with respect to the emergency situation. The use of training platforms allows for the manipulation of a number of design variables relevant to improvisation, including risk, dynamism, stress, information structure, and feedback. Many available training platforms lack the capability to handle the dynamics that arise during emergency response operations. For example, HAZUS is used in the United States mainly for disaster planning at the local, state, and federal levels. Because of the limited possibility to include dynamic information and because it is a stand-alone tool, this system can mainly be used in a static way during emergency response training. There is an increased use of information technology–intensive training systems for tabletop, functional, and full-scale exercises.

A number of opportunities for further development of information technologies may be identified from this discussion.

Generation of more realistic scenarios: Specialized simulation systems may be used for scenario generation.

Interactive simulation-based training: Simulation systems (typically real-time simulations) vary from use for individuals to larger groups. The larger the group, the more technologically challenging and expensive the systems are. Distributed simulation systems are typically used for training of groups. Systems for first responders and incident managers may also use virtual reality technologies.

Training evaluation: This set includes tools for logging and analyzing the decision process, such as video and audio recording of individuals or groups, keyboard logger, event logger for software packages, and tools for automatic report generation.

Critical Applications

As businesses move closer and closer to having all of their tools available through computing, many risk and business continuity managers are today focusing their efforts on ensuring that systems, or applications, are always available to ensure that productivity continues and that business operations do not stop. But through this increased emphasis on making applications available, or quickly recoverable during a time of crisis, a more thorough process has been designed to take into consideration which applications must recover the quickest, which ones can take a lower priority, and how much it costs to ensure that the proper technology is in place in order to accomplish these goals. Through these discussions, a stack ranking, or what is more commonly referred to as "criticality," has been designed in order to balance the goals of ensuring that applications continue to operate while keeping within an organization's allocated budget constraints. Most common classifications today for applications range from the lowest priority, sometimes called "Deferrable," to "Import," to "Critical" or what some term "Mission Critical." All of these classifications have different meanings, recovery thresholds, and, of course, costs to maintain the level of assurance to the business.

Determining and Classifying as Critical

There are many aspects to determine what applications can, and will be, classified as critical to a business or government operation. Some operations design their own system of making these determinations, considering factors such as the industry of the operation, how large the business is, available budget and resources, and general leadership buy-in on the design and expense. But from an industry-generic standpoint, determining an application as critical lies mainly on a few factors based on questions: If the application was not available to your business for more than 24 hours, would you then experience a large financial impact? Would your reputation from a customer standpoint suffer, and would that application have any dependencies with other applications with which it interacts? If you answer yes to these questions, you more than likely have a critical application on your hands, and you will need to incorporate a strategy into your operation to ensure that you protect that application, as well as its data, to ensure that you can recover it very quickly during a time of crisis. Of course, many more detailed questions will have to be asked once you have made the initial determination that an application is critical.

Assessing Critical Applications Objectives

Anyone even peripherally connected to information technology recognizes that the number of business-critical-level applications has dramatically increased in the last few years. However, the levels of availability required for each application vary dramatically. Assessing each application's availability requirements allows storage and networking administrators to target appropriate solutions.

Although assessment of application criticality may be relatively simple for some businesses and government operations, in most cases the process can be complex and time-consuming. This is especially true of applications that have evolved over a period of time with nonuniform development processes. Dependency among applications contributes significantly to this complexity. For example, if Application A relies on a feed from a database controlled by a separate Application B to provide mission-critical information, having complete redundancy for A will be of no use if B is not available. Some of the steps to be taken in the assessment process include listing all your applications, identifying dependencies between applications, creating application groups based on dependencies, prioritizing application groups based on importance, and associating availability metrics for application groups and applications within groups.

Two key metrics that identify the level of availability required for applications and data, especially in a disaster recovery scenario, are recovery time objective (RTO) and recovery point objective (RPO). Recovery time objective measures the acceptable time for recovery. RTO poses the question, How long can the application be down? Cost and downtime implications determine RTO for a given application. There have been several studies on the cost of downtime for specific market segment applications in retail, telecommunications, manufacturing, e-commerce, energy, and financial services. These studies often take into account not just the short-term tangible loss in revenue but also the intangible long-term effects. Although these studies provide useful data, organizations can greatly benefit by performing a thorough assessment customized to their environment.

RTO for an application, in turn, helps determine the tools and technologies required to deploy the appropriate availability level. For example, if the RTO for a given application is seven days, then restoring from backup tapes may be adequate. On the other hand, if the RTO is a few minutes, wide-area replication and failover may be required in case of a disaster.

Recovery point objective measures the earliest point in time to which the application and data can be recovered. Simply put, it seeks to determine how much data can be lost. The nature of the particular application typically determines the RPO. In case of a major data center outage, it may be acceptable for certain applications to lose up to one week's worth of data. This could be from a human resources application, in which data can be re-entered from other document sources.

Once again, as in the case of RTO, RPO helps determine the tools and technologies for specific application availability requirements. If, for example, the RPO for a human resources application is indeed determined to be seven days, then restoring from backup tapes may be adequate. However, for a banking application that deals with electronic funds transfer, the RPO is likely to be seconds—if that. In this case, in the event of a data center outage, nothing short of synchronous data replication may suffice.

Overall, when assessing your objectives, ensure that you are asking the right questions that pertain to your operations in particular, and then design a methodology around your functions.

Critical Applications Methodology

For a lot of business and government operations, once the initial determination of an application being critical to ongoing operations has been made, many ask themselves what they need to do in order to ensure that this application is highly available, and, of course, quickly recoverable after a crisis. Many operations are often found floundering in the deep waters of information technology (IT) expense, consultant assessments, competing priorities, and the sheer myriad tools available to help them protect their investment. One thing is for sure: As we continue to immerse ourselves in technology, there will be more available tools and assistance to help you wade through all of the different aspects, so don't expect things to get any clearer from the standpoint of options from which you should choose. From a simplistic standpoint, though, to incorporate a critical applications methodology into your operation, you must consider designing a process for this around your operation that will meet your goals of protection, keep your costs to a reasonable amount, and bring a level of resiliency to your business continuity in order to make a good return on investment (ROI) statement to your leaders. Some operations simply back up their data more often, or in a different manner, so they can recover quicker; some design more sophisticated solutions such as having the critical application set up at a disaster recovery data center site, and/or bring in a virtual, or cloud-based, application that lives at a separate location owned by a data center company (commonly referred to as a colocation site) that ensures available uptime for your application. Either way, having some form of a methodology in place to ensure that your business or government operation is more resilient is a progressive policy.

Proper Recovery Testing

As plans are designed and documented to implement critical applications to a business or government operation, a robust testing process must be designed and exercised to ensure that your solution actually will meet your recovery goals. Many businesses today test designated critical applications on an annual basis, and some test the resiliency, or strength, of their plans more often than that, depending on the impact to their operations.

Incorporating your critical applications testing into your disaster recovery plans is essential for their survival; without a strong partnership between the organization's business continuity management (BCM) and information technology (IT) disaster recovery teams, the chances of having a successful testing strategy, and therefore a successful test itself, are severely compromised.

Some organizations create testing of critical applications with relation to the most common incidents that cause crisis situations, but other organizations rely more on a more generic fact of "system down" scenarios. Either focus point is effective in designing a proper test plan, but the most important component of any recovery plan is the specific procedures needed to restore the critical applications.

The development of a testing strategy requires key business decisions to be made regarding the level of frequency of testing needed to ensure that recovery objectives can be achieved during a disaster. The complexity and frequency of testing are based on the risk to the business or government operation. Even small institutions should participate in tests with other critical components of the business (such as operations processes). Keep in mind that unmanned recovery testing, where backup tapes are sent to the recovery site to be run by service provider employees, is not a sufficient test of an institution's plans.

Testing strategies should exhibit the conditions and frequency for testing critical applications. The strategy should include what objectives you are seeking and schedules, as well as a function for reporting on the results to leadership. Proper evaluation of risks to the business is essential, taking into considerations such as whether you will need full or partial operational capability during a crisis, will you have the workforce to support the critical application, and will you have a reduced demand for your services during a crisis. Mainly, validation of your assumptions to ensure they are appropriate for your requirements is also a key indicator that you have developed a strong test plan to support your critical applications.

Adding Business Value

Today, critical applications and the data that support them are the heartbeat of continued operations, for they make your operation unique; therefore, protecting the critical operations that drive these data is vital to your survival. More important, ensuring that your data are available goes beyond responsive actions to unplanned failures. It encompasses a proactive approach that leads to competitive advantage, which automatically brings more value to your operation. This advantage is built when your customers not only are loyal but also become promoters of your organization because they know they can depend on you, and having a resilient plan for critical applications is a key ingredient in gaining this support

In today's highly competitive business environment, business interruptions resulting from system outages can be devastating. Regardless of the cause—hurricane, fire, accident, computer virus, or even user error—downtime can be not only costly but also in some cases catastrophic. With a mobile workforce, global customers wanting to do business around the clock, and continually greater dependence on technology, you need to not only protect your critical applications but also continue business operations virtually uninterrupted. The cost of downtime, depending on the industry, can range from thousands to millions of dollars per hour—due not only to disaster recovery expenses but also to lost sales, customer defection, financial penalties from violation of legal requirements, and lack of productivity. Add to that a damaged reputation in the marketplace and diminished shareholder confidence, and the cost of downtime can be staggering. Knowing how to properly identify and then manage your critical applications during times of crisis can be the defining factor between incurring multiple forms of damage to a business versus a quick recovery and a solid reputation that your customers and users can count on.

Critical Business Functions

When a problem affecting critical business functions cannot be handled by normal problem-management processes, the problem escalates to a crisis. The crisis-management process helps control the response to events that impact critical business functions. To successfully manage a crisis involving critical business functions, those business functions must be identified and prioritized, and methods of handling the possible impacts should be planned. Once a set of possible responses is planned, the handling of the crisis should become easier and result in the quick resumption of those critical business processes. In addition, the process of identifying and prioritizing the critical business processes may also find ways to prevent impacts to those processes to avoid a crisis.

Business Continuity Life Cycle

The business continuity life cycle is a good way to plan for events impacting critical business functions. The business continuity life cycle will identify business functions and determine their priority within the organization. The business continuity life cycle will also attach the impact of interrupting each business function in the form of lost revenue and additional costs. Typically, the business functions that provide the most revenue or would result in the most cost are considered critical business functions. The business continuity life cycle process lets decision makers finalize the priority of critical business functions in what is commonly referred to as the business impact analysis.

Hazard Vulnerability Assessment

Along with the business continuity life cycle, there is the hazard vulnerability assessment, which attempts to list the possible threats to a critical business function and gauge the vulnerability to those threats. The hazard vulnerability assessment ranks the threats according to how vulnerable an organization is to those threats, yielding a prioritized list of threats. That list is matched to the prioritized list of business functions in the business impact analysis, and where the high-vulnerability threats would impact the high-priority business functions, plans are made to prevent and mitigate the impact. Critical business functions very often make use of technology and have a significant number of people involved. Some critical business functions also require specialized skills from the people who perform those functions.

Business Continuity Plan

Once the critical business functions have been prioritized, two planning processes should be conducted that will produce written plans. The first is the business continuity planning process, and the second is the disaster recovery planning process. The business continuity plan prepares procedures that will enable critical business functions to be performed in the absence of the usual technology. Business continuity plans often involve performing the critical business function using manual processes. It is very good when manual processes can be used because it may be a while before technology can be reacquired. Another method that can be incorporated into the business continuity plan is to use the more available technology that has not been impacted, such as applications on personal computers. Sometimes temporary processes using a PC and its applications can successfully perform critical business processes, and then later, the information stored on the PC can be sent to the recovered information technology environment. In this way, when a crisis develops, the business continuity plan will allow the critical business function to operate until the technology can be recovered by the disaster recovery plan.

Disaster Recovery Plan

The disaster recovery plan prepares procedures to recover the technology normally used for the critical business functions. There are many ways to recover technology, but any recovery method must be compatible with the possible outcomes of the threats and vulnerabilities. For example, it may not be a good idea to plan to recover the technology in the same building that was just destroyed. Instead, a disaster recovery site can be obtained to hold the recovered technology until the destroyed building can be salvaged. Because there are costs associated with a disaster recovery site, the planning should specify what type of site would work best. There are hot sites, where preconfigured equipment is running and waiting to take over as the primary data processing site. There are cold sites that consist of just raised floor space and climate control where replacement equipment can be shipped, then configured, and then used. There are also warm sites, where there is some raised floor for replacement equipment and also some hot site characteristics in that some equipment is there, running, but not enough to recover everything—just enough for the most critical applications. In addition to the site where the recovery will take place, there is also need for backup media on which the vital information will be stored. There are many considerations for backup media that will affect how a recovery is performed. There are many options, and an organization new to disaster recovery planning should enlist the assistance of a trained disaster recovery planner.

Succession Plans

Another important planning item is to have a line of succession for key people and alternate places to get the skilled workers necessary to perform the critical business function. Key people should have at least three alternative members of the organization who can make the same decisions in case the key person is not available. Skills can usually be obtained from temporary help organizations that have the people whose special skills are required.

Insurance

Planning ways to prevent and mitigate the impacts to critical business functions is not without some cost. The business continuity plan and the disaster recovery plan identify equipment and services that will help execute the business continuity plan and the disaster recovery plan. To help with the financial side of things, there are several types of insurance an organization can obtain. Some of those insurance instruments are called business interruption insurance, lost revenue insurance, and key person insurance. Each assists with the financial side of the problems they name. Of course, to make a claim for any insurance, a detailed list of equipment and skilled people needs to be maintained because the first thing a claims adjuster will ask for is proof that the insured items are lost.

Invoking the Plans

The activities in the business continuity plan and the disaster recovery plan and the process for making claims for insurance all become part of, and are controlled by, the crisis management process. Immediately after the event invokes the crisis management process and the assessment of the crisis says critical business function will be halted for a predetermined period of time, the commands are given to begin any business continuity processes. When it is evident that the technology will not become available for a predetermined period of time, the disaster recovery plan should be invoked and a disaster declared by the organization. As the impacts and damages are documented, the commands are given to initiate claims processes with the insurer to provide funds for the recovery.

Incident Command System

Crisis management can be a very chaotic process. It is best to have a specific way to conduct the crisis management process. One proven method is the Incident Command System (ICS), is a standardized, on-scene, all-hazards incident management approach that has been developed and proven successful over many years of crisis management. It is a very organized approach to handling a crisis involving many organizations and many people. The ICS can be scaled to any event, large or small, as well as any type of participant. Training on the ICS is also free from the Federal Emergency Management Agency's Web site.

Conclusion

Prior to a crisis that impacts critical business processes, the business continuity life cycle should be used to plan for the prevention and mitigation of impacts to the critical business functions. These plans will be invoked by the crisis management process as needed at predetermined intervals based on information obtained about the event and its impacts. The plans consist of the business continuity plan, the disaster recovery plan, and the various insurance coverage. When the normal problem management processes fail to handle a problem affecting critical business functions, the crisis management process is invoked to control activities and expedite the recovery of the critical business processes. With proper control of the activities in the crisis management process, an organization can respond to a crisis and limit the impact to its critical business functions.

Critical Infrastructure

Infrastructure comprises the facilities and equipment needed for the operation of society or an enterprise. It has both physical and organizational aspects, and hence the term covers facilities (such as buildings, roads, and bridges), sites, systems, and networks, including electronic communications. The term *critical infrastructure* refers to those elements that are absolutely necessary to support the basic functioning of society and the essential services upon which it depends. The loss or inefficiency of these assets would lead to severe economic and social consequences, and in the worst cases there could be loss of life.

In any classification of critical infrastructure, the main sectors are water, energy, food, health, transportation, communications, finance, government, and emergency services. These, in turn, can be subdivided as follows:

- *Water:* dams, treatment plants, pipelines, sewers
- *Energy:* power stations, transmission lines, transformer and switching stations
- *Food:* warehouses, distribution networks, sales points
- *Health:* hospitals, emergency systems, pharmaceuticals
- *Transportation:* road, rail, air, water (including airports, sea ports, highways, railway lines, and bridges)
- *Communications:* land-line and mobile telephone systems, cyberspace
- *Finance:* banks, money supply, financial services
- *Government:* national, regional, local
- *Emergency services:* fire, police, ambulance, specialized response

The critical nature of infrastructure can also be viewed in terms of geographical scale, and in this context it can be classified as national (of importance to the functioning of national life) and local (of importance to the functioning of local affairs).

Essentially, three kinds of hazards threaten critical infrastructure: extreme natural phenomena include floods, storms, earthquakes, and volcanic eruptions, distributed according to the prevailing geography and temporal pattern of such events; technological failures, which are complemented by the damaging effects of human error; and intentional events, such as those associated with terrorism and sabotage. The elements of critical infrastructure may be vulnerable and exposed to these hazards either singly or in combination. Vulnerability refers to the propensity for harm, while exposure can mean either that the assets are under threat for given periods of time or that they are at risk of possible loss to a given extent.

Measuring the Risks

Damage to critical infrastructure during an extreme event may cause both direct and indirect effects. The former comprise interruption of service, destruction of assets, and losses of capability that arise directly from the phenomenon that causes the harm. The latter result from "knock-on," or cascading, effects, for example, pollution of the environment following natural hazard damage to an industrial plant.

In the case of critical infrastructure, although there is a prima facie case for risk aversion, this is usually too expensive to contemplate, with the exception of high-reliability systems, such as civil aviation, for which exceptional measures are both warranted and supported by public intolerance of the risks. Instead, for most forms of critical infrastructure, risk is managed using the "as low as reasonably possible" (ALARP) concept.

This poses two arbitrary thresholds: one of them defines unacceptable risk, and the other pertains to broadly acceptable risk. Risks that fall above the former threshold must be reduced,

U.S. Small Business Administration Administrator Karen Mills (left, front) and other federal and city officials survey storm damage in Alabama from the April 27, 2011, tornado, which killed 72 people in four states. Tuscaloosa Mayor Walt Maddox said the area's infrastructure was decimated by the tornado. Among the infrastructure losses were a fire station, the police department's east precinct, a communication tower, and a facility that contained the Emergency Management Agency and Environmental Services Departments.

either because the consequences of failure are unacceptably high or because there is strong and fairly unanimous support for investment in risk-reduction measures. The second threshold is defined by consequences that are not sufficient to render the infrastructure inoperative in any but the most improbable circumstances. Between the two thresholds is an area in which it is opportune to reduce the risks to the lowest possible level, conversant with reasonable expenditures and available—and acceptable—methods. In this process, it may be necessary to demonstrate openly that ALARP has been applied, which can usually be achieved by showing that the methods are appropriate, reasonable, sustainable, and justifiable in terms of costs, efficacy, and predicted reductions in losses. A useful acronym for this process is SMART: Specific, Measurable, Attractive (or acceptable), Realistic (or realizable), and adequate in terms of Timing.

Whether or not infrastructure is critical can be judged by establishing a threshold. This involves assessing the threat to assets (either singly or in groups or clusters) in terms of how their total or partial loss will affect normal life, economic activities, and the provision of essential services. For example, the United Kingdom (UK) uses five levels of criticality, ranging from cases in which losses would be negligible to those in which the destruction of particular infrastructure would have a catastrophic impact on the nation. The UK also has a basic crisis management law (the Civil Contingencies Act of 2004) that designates the operators of critical infrastructure as "second category emergency responders," with a statutory responsibility to prepare for emergencies.

By way of example, very many ordinary transactions are dependent on the availability of banking services, without which salaries cannot be paid and goods and services cannot be procured. In a similar vein, the loss of electrical current would cause grave problems for medical procedures, transportation, commerce, and a host of other activities. In both cases, the problems would tend to become dramatically worse the longer the service interruption lasts. Hence, planning and protection are essential to the maintenance or quick restoration of vital services. For particular structures, services, or groups of assets, a criticality threshold can be established by ascertaining whether their loss would pose serious problems for the conduct of normal daily life. Above a certain level of loss, the infrastructure affected can be classified as critical and of national or local importance. The problem is also a dynamic one. In some cases, short outages may have only nuisance value, but longer interruptions may be very serious. For example, volcanic ash in the atmosphere may curtail civil aviation, as happened for almost one week in Europe in April 2010 with the eruption of the Icelandic volcano Eyjafjallajökull. Airlines and businesses that depended on airlines suffered losses, but a longer period of inactivity would have led to a rash of bankruptcies among strategically important industries, not least the airlines themselves.

To prioritize interventions for the protection of critical infrastructure, a risk matrix can be used. This classifies the level of harm that is likely to occur to an asset or group of assets and compares that with the probability of an adverse event. High probability of a crisis and great sensitivity to losses add up to a strong priority for intervention

Case Study: Earthquake Threats to Water Supply Infrastructure

Water supply systems and networks are part of a nation's critical infrastructure. In seismic zones, the first task is to assess the nature and magnitude of the threat to the system.

Seismic microzonation can be used to subdivide geographical areas occupied by the infrastructure according to the pattern of hazards. This usually involves analyzing the historical record of seismicity, including return periods and local magnitude-frequency relationships. It also requires geologists and seismologists to scrutinize the local stress field in the Earth's crust and make projections of the slip rate of local faults. Microzonation maps can show the potential for ground shaking, sedimentary and topographic amplification of seismic waves, liquefaction susceptibility, lateral spreading, landslides, rockfall hazards, and earthquake-related flooding. Moreover, the assessment of seismic risk to dams and reservoirs can help define potential failure inundation (that is, floodable) areas.

Maps of peak ground acceleration (PGA) or peak ground displacement (PGD) can depict the potential for damage to buried lifelines. If liquefaction (the spontaneous transformation of ground from the solid to liquid state under earthquake loading) is possible, a liquefaction potential map can be drawn up. The interaction of the water distribution infrastructure with the performance of different terrains can be analyzed in relation to a map of seismic amplification. An earthquake response spectrum can be calculated in order to represent peak acceleration, velocity, or displacement response of a structure or system with a particular natural vibration period and a fixed damping ratio (damping refers to the forces that resist vibration). These calculations and mapping exercises are conducted in relation to a design event, which is usually conceived of as the maximum credible earthquake (MCE).

A geographic information system (GIS) should be used to compare the seismic data described above with the pattern of water supply lines. After an earthquake, damage data can be added as a map overlay. Appropriate mapping scales are 1:50,000-1:100,000 for subregional networks, 1:5,000-1:10,000 for local networks, and 1:1,000 for a specific plant, such as a water treatment facility.

to reduce the risk. Once again, the matrix may need to be viewed in terms of a dynamic reality, in which risks vary over time, are possibly cumulative, or increase nonlinearly as a result of a protracted crisis.

Protecting Critical Infrastructure

The process of critical infrastructure protection may involve programs, plans, activities, or, better still, all three. Once an asset or group of assets has been identified as of critical importance, the first action should be to assess its weaknesses. This may involve creating scenarios of what is likely to happen in a crisis and how the infrastructure is likely to perform under duress. The second stage is to create resilience and redundancy. This may involve "hardening"—that is, making the assets more robust, so their performance does not deteriorate significantly under stress. At the same time, protection measures can be created, including structural measures, such as building techniques designed to resist impacts, and nonstructural approaches that rely on procedures and plans to counter the effects of an emergency. Design that is tolerant of faults can be used, and so can "fail-safe" design, in which measures are taken to ensure that the effects of damage or destruction are relatively innocuous.

Resilience may involve maintaining adequate levels of operating supplies and ensuring that reserves of manpower are sufficient. Contingency and emergency plans must be drawn up and kept current. They must also actively involve top management. The plans should include procedures for restoring essential services in the event of any interruption. In most cases, they will be based upon credible scenarios for failures and disasters. Finally, most critical infrastructure protection involves redundant systems. For example, hospitals depend so heavily on continuity of electrical supplies that they usually have diesel generators that will start up on the instant that power supplies are interrupted. This limits the danger of, for example, spontaneous interruption of surgical operations that require lighting and power to life-support systems. Nevertheless, the autonomy of generators is limited by available diesel fuel reserves and supplies.

Before design standards can be adopted in order to protect critical infrastructure, interdependencies must be measured and protection strategies must be evaluated. If safety-critical objectives need to be adopted (and they are a mark of the criticality of infrastructure), then design should ensure performance levels that are capable of withstanding the greatest shocks to the system that can be envisaged. With respect to "normal" (that is, noncritical) infrastructure, this may appear to be overdesign, but in the event of a highly abnormal crisis, it will be well justified.

Like other assets at risk, critical infrastructure may be subject to cost-benefit evaluation of any investment in protecting it. Crude logic suggests that investment in protection measures should cease once equality is achieved between cost and benefit. However, the hidden costs of not protecting critical infrastructure may change the picture. Hence, there is a greater propensity to invest in apparently disproportionate measures, because the infrastructure is strategically important and because its loss or inactivity would lead to exceptionally serious or unduly expensive consequences.

Most governments would recognize the value of putting into practice a comprehensive program of critical infrastructure protection. This would involve looking systematically at the list of essential physical, socioeconomic, and information technology assets and creating a strategy to invest in their protection on a prioritized basis. This should be an ongoing process, as development and growth constantly change roles, relations, and the value of the assets.

Criticality Assessment

Although criticality assessments may be conducted for a variety of potential hazards, the events of September 11, 2001, have seemingly permanently linked the term to thoughts of terrorism. In an attempt to demystify the process, consider that we all perform criticality assessments in life, and typically do so at an early age. In fact, we often perform criticality assessments without even considering what we are doing. Imagine sitting in front of a chessboard across from a very capable opponent. You have the move, and in preparation you consider where are you vulnerable, where the opponent is vulnerable, and what are the consequences of a variety of moves available to you. As you consider these things, you are in part performing a criticality assessment of your own pieces, and also of your opponent's.

A more formal criticality assessment requires more consideration than a chess game and uses methodologies and tools to help make determinations about where and how to deploy available resources and assets. Criticality assessment is different from risk and vulnerability assessments but incorporates them into the matrix of consideration. Criticality assumes limited resources, meaning that there are not enough to harden every perceivable potential loss. At the very base of purpose, criticality assessment is a process that serves as a tool for helping identify those assets most critical to continuity of operations/existence. When we identify the assets most critical to us, we can more wisely apply available resources to protect them.

Before engaging in criticality assessment, it is important to understand that it is a tool in many varieties; there us a plethora of methodologies and matrices to assist in the process. The fact is that two people performing criticality assessments in the same organization may arrive at different outcomes; there is some subjectivity in assessing what constitutes the greatest criticality. The process of assessment requires some level of predictability, which will also contribute to different outcomes. Determining success in criticality assessment is extremely difficult; proving the fact that an event did not occur as the result of proper critical assessment is seemingly impossible.

Criticality Assessment as a Process

In 2003, President George W. Bush issued Homeland Security Presidential Directive 7 (HSPD-7)—Critical Infrastructure Identification, Prioritization, and Protection. The directive title identifies the basic structure of the process of performing a criticality assessment: identification of critical infrastructure, prioritizing the importance of each element, and implementing appropriate protective measures. The process is essentially the same for any dimensions of assessment; the same three basic steps are followed in reviewing a facility or network of facilities, a small community or a large metropolitan area, an individual state, or a nation of them.

Step 1—Infrastructure identification: The 2003 Bush directive essentially expands on President Bill Clinton's 1998 Presidential Decision Directive—63 (PDD-63)—Protecting America's Critical

Infrastructures. The 2003 directive expanded the listing of infrastructure sectors from those listed in 1998. Other presidential papers have identified different listings from these two; in fact, today there are multiple lists of critical infrastructures. This points directly to one aspect of the difficulty of performing a criticality assessment: determining what constitutes a critical infrastructure.

In their 2003 report for *Congress, Critical Infrastructures: What Makes an Infrastructure Critical?* John Moteff, Claudia Copeland, and John Fischer identified four paradigms of consideration that seemingly explain the multiple lists: national defense, economic security, public health and safety, and national morale. Combining the list for each of the four paradigms produces a list of 20 sectors: telecommunications information networks; energy; banking/finance; transportation; water; emergency services; government; health services; national defense; foreign intelligence; law enforcement; foreign affairs; nuclear facilities, in addition to power plants; special events; food and agriculture; manufacturing; chemical; defense industry; postal and shipping; and national monuments and icons. This listing can be adapted to give meaning and structure to the identification of assets for any criticality assessment.

Once the list is adapted to fit the assessment being performed, the structures can be identified and assigned to the appropriate sectors. The creation of a list based on sectors helps the identification process by prompting ideas about what

Case Study: Critical and Noncritical Infrastructures

Following the issue of President George W. Bush's Homeland Security Presidential Directive 7 (HSPD-7)—Critical Infrastructure Identification, Prioritization, and Protection—federal agencies assigned employees to perform criticality assessments of infrastructures relating to each agency's function. One of these was the U.S. Army Corps of Engineers, and an individual was assigned to identify critical infrastructures in a rural southern state.

Eager to complete the tasks, the individual simply chose to view everything owned or operated by the corps as critical. The state police agency received a very complex and long listing of requests for troopers to be assigned to critical assets. Although the state police agency stood ready to protect critical infrastructure, the listing required more personnel than there were troopers. A command staff officer contacted the corps' representative and explained that the agency had to continue its primary enforcement mission, that there were fewer personnel than had been requested to cover corps resources, and that other agencies were also requesting assistance. The corps representative contacted the governor's office and requested "immediate assignment of all available troopers" and suggested that consideration be given to augmenting them with activated soldiers of the U.S. Army National Guard.

The governor's office contacted the senior-level corps official in the state, and a meeting was arranged to discuss the matter. During the meeting, it was determined that in the original assessment every asset was regarded as critical; a 50-space wilderness campsite was included, as were all boat launches on the corps' lakes and navigable rivers. A more reasonable assessment found two corps reservoirs that were prioritized as critical. One reservoir was the cooling and water source for two nuclear reactors used in the production of electricity; the other had significant housing and other critical infrastructure in the potential flood zone if the dam were compromised.

Other infrastructure components were prioritized as essential, including all locks and dams. During the reevaluation process, it was determined that many of the campgrounds prioritized as critical were on a corps closure list that had been previously developed as a budget-cutting measure. Apparently no regard had been given to available data during the original assessment.

This case study makes plain the need for a structured and reasonable approach to criticality assessment.

assets are essential to continuity of operations. Not all assets will fit into the identified sectors, but not all assets are critical.

Step 2—Prioritization: The concept of prioritization helps identify assets that are most critical to the continuity of operations. This facilitates a determination of which assets to address first, based on their high criticality. Prioritization also allows logical determinations about where to utilize available resources; again, the most critical assets would be selected first. There are a variety of available models to use in determining prioritization, some being quite complex and others very simple. Prioritization is that part of criticality assessment that most nearly represents a quantitative methodology.

A simple model uses three levels of prioritization: critical, essential, and nonessential. An infrastructure or asset is critical if it is vital to continuity of operations or essential to the life safety of individuals. Those things classified as essential are important but would only present a difficulty if unavailable. Nonessential things are those that would pose an inconvenience.

A more complex model includes consideration about the cost of replacement, downtime until a replacement can be installed and operational, and availability of outsourcing. Some of the more complex models include a threat assessment, whereby a determination is made about how likely the asset is to be destroyed by natural disasters or human-made events.

Taken to an individual family level as an example, consider that those things critical to life safety are food, water, some medications, and shelter. Those things that are essential include clothing and sanitation. Most other things fall into the nonessential classification; having electricity is nice, but as many people in the world do, we can survive without this relatively recent innovation. Prioritization becomes more difficult with the complexity of the thing being assessed, since it is easier to assess a smaller town that a large metropolitan area; but the available resources may be less for the smaller town. Once the prioritization is complete for each sector, the task begins of prioritizing across them. Using the individual family model again as an example, once the determination is made of those things critical, it becomes necessary to determine which comes first. Even in this very simple example, it may become advantageous to consider recovery time.

Recovery time can be situational to the event and other conditions, such as weather. Although in our family-level example drinking water is more critical than shelter, there are situations where this may not be accurate. Consider that the environment is one of sub-zero temperatures; shelter would take precedence over water. Consideration of recovery time works similarly. Consider that the loss of available drinking water could be remedied in a couple of hours, but having an available food source could take months. Prioritization would put food ahead of water, since the water is easily replaceable. Applying the principle of Maslow's hierarchy of needs to prioritization sometimes helps to understand and focus on what constitutes the critical, and distinguishes the essential from the nonessential.

Step 3—Protection: The third step in addressing protection of critical infrastructure is the outcome of the critical assessment process. The purpose of the critical assessment is to identify and prioritize, but protecting becomes another function. Still, consideration must be given to protection to determine if that process impacts the findings of the original critical assessment. This obviously hints that the process of critical assessment is not a single one but an ongoing reevaluation.

Critical Assessment Benefits

Utilizing critical assessment produces positive benefits. One benefit is heightened awareness of the value of assets and of threats and vulnerabilities opposing them. Another benefit is the realization of the true level of interdependence within the thing being assessed. There is also evidence that performing critical assessment promotes interagency and interdepartmental cooperation, again because of the understanding of interdependence that is made evident in the process.

Critical Assessment Evolution

There is little doubt that with the growing body of research and experience in critical assessment, there will be new tools introduced, and eventually there will be definition given to best practices. There is a growing number of educational programs offering higher education courses, even at the graduate level, in critical assessment. There is also a growing number of critical assessment professionals and private firms now contracting to perform services for those in both the public and private sectors. As the critical assessment process becomes more professional, there will likely be greater definition given to terminology, sector identification, and process. The performance of critical assessment must be evolutionary, but it is also true that the functional process itself is evolving.

Cyber Crime

Cyber crime is a relatively new kind of criminal activity that encompasses all the ways in which computers and other types of portable electronic devices capable of connecting to the Internet, such as cell phones and PDAs, are used to break laws and cause harm. In a more technical sense, it refers to the use of computers or other electronic devices via information systems such as organizational networks or the Internet in order to facilitate illegal behaviors. Cyber crime has developed and evolved alongside the Internet and the proliferation of other advances in information technologies. The term *cyber crime* is sometimes used synonymously with technological crime, high-tech crime, Internet crime, and digital or electronic crime.

Although cyber crime has entered into common usage—discussed in political, criminal justice, media, public, and academic discourse in diverse sources including academic journals and newspaper articles—there are dramatically varied views of what cyber crime is. Legal definitions vary drastically among jurisdictions and law enforcement agencies charged with tackling it. In the academic arena, there is no consensus whether cyber crime is a new form of crime qualitatively different from “terrestrial crime” or instead consists of criminal activities pursued with new tools and techniques.

According to some authors, cyber crime takes place in cyberspace, a novel sociointeractional environment with certain features (the collapse of spatial–temporal barriers, many-to-many connectivity, the anonymity and plasticity of online identity) that make possible new forms and patterns of illicit activity, inexorably altering the relationships between offenders and victims and challenging the potential of criminal justice systems in order to offer satisfactory solutions requiring the development of a correspondingly innovative criminological vocabulary and conceptual apparatus. For skeptics, cyber crime is essentially the same as the familiar terrestrial crime, which means that there is no need for the development of new criminological theories.

This lack of consensus on a definition of cyber crime impacts every facet of prevention and remediation. On the other hand, there is significant confusion among academics, computer security experts, and users about the extent of real cyber crime, although research shows that the number of people and businesses impacted by various types of perceived cyber crime is growing, with no signs of declining. Cyber crime is a global problem that costs an estimated $50 billion annually. The number of victims and cost of cyber crime will inevitably rise with the number of Internet users.

Types of Cyber Crime

Definitions of cyber crime differ depending on the perception of both observer/protector and victim. The phenomenon also has many different facets and occurs in a wide variety of scenarios and environments. The Council of Europe's Cybercrime Treaty uses the term *cyber crime* to refer to various offenses ranging from criminal activity against data to content and copyright infringement. Gabriole Zeviar-Geese suggests that the definition is broader, including activities such as fraud, unauthorized access, child pornography, and cyberstalking. The United Nations Manual on the Prevention and Control of Computer Related Crime includes fraud, forgery, and unauthorized access in its cyber crime definition. Probably the most appropriate definition is that cyber crime is any crime that is facilitated or committed using a computer, network, or hardware device. The computer or device may be the agent of the crime, the facilitator of the crime, or the target of the crime; indeed, the crime can take place on the computer alone or in other nonvirtual locations.

Secretary of Homeland Security Janet Napolitano observes agents working to identify cyber crime activity and protect victims at the Immigration and Customs Enforcement's Cyber Crimes Center in Washington, D.C., on December 19, 2011.

Sarah Gordon and Richard Ford suggest that there are two main types of cyber crime. Type I, more technical in nature, has the following characteristics:

- It is generally a singular, or discrete, event from the perspective of the victim.
- It is often facilitated by the introduction of crimeware programs such as keystroke loggers, viruses, rootkits, or Trojan horses into the user's computer system.
- The introductions can be, but may not necessarily be, facilitated by vulnerabilities.

This type of cyber crime requires that data be protected from traditional threats such as viruses and worms; however, it is also necessary that users be cognizant of the concept of vulnerabilities.

More human in nature is Type II cyber crime, at the other end of the spectrum, which includes (but is not limited to) activities such as cyberstalking and harassment, child predation, extortion, blackmail, stock market manipulation, complex corporate espionage, and the planning or carrying out of terrorist activities online. The characteristics of Type II cyber crime are the following:

- It is generally facilitated by programs that do not fit under the classification of crimeware. For example, conversations may take place using IM (instant messaging) clients or files may be transferred using the FTP protocol.
- There are generally repeated contacts or events from the perspective of the user.

In reality, cyber crime presents a continuum ranging from a crime that is almost entirely technological in nature to a crime that is, at its core, entirely human related.

Because of the transnational character of cyber crime, there are significant law enforcement, regional, multinational, and global efforts to fortify the legal battle against cyber crime internationally. In 1990, the United Nations General Assembly adopted the Guidelines Concerning Computerized Personal Data Files, and it has endorsed several resolutions in order to improve cyber security awareness at both the international and the national levels. The General Assembly invited states to consider the measures in their endeavor to fight the criminal misuse of information systems, and it has decided to maintain the question of the criminal misuse of information technologies on the agenda of its future sessions. The Council of Europe Convention on Cybercrime is acknowledged as a landmark in the sphere of the international harmonization of cyber crime law.

Cyber Security

The term *cyber security* denotes a number of activities, measures, and techniques developed to protect from attacks, service interruptions, and other threats to computers, computer networks, and information they contain and exchange, as well as software, data, and other elements of cyberspace. Therefore, this term refers to united efforts and attempts, which include research and analyses, with the aim of inventing new technologies and improving the existing activities related to the security of cyberspace and the level of its protection from cyber threats. Those activities can contain, for example, an estimate of reliability and vulnerability of the hardware and software used in critical infrastructures of a particular country. The concept of cyber security implies a holistic approach in research and confronting cyber threats to information systems—from standpoints of information and mathematic sciences and their special disciplines (like cryptography and cryptanalysis), and military, legal, crime, and criminology aspects.

Etymologically, roots of the term *cyber security* date back to the 1960s. At that time, communication security (COMSEC) was dealt with. When computers appeared, during the 1970s, computer security (COMPUSEC) came into being. In the 1980s, because of such threats as Cuckoo's Egg and Morris Worm, it was realized that a network consisting of a large number of computers could be used for malicious aims. That is when the integration of communication and computer security happened, so the term *information security* (INFOSEC) was coined. Information security has integrated disciplines that used to be separated, such as personnel security, computer security, communication security, and operational security. At that point, information security had already become one of the four cornerstones of U.S. national security (besides diplomacy, economy, and military components).

Definitions of Cyber Security

Today, there is no generally accepted definition of the term *cyber security*, but the terms *information security* and *information assurance* are part of a wider concept of cyber security.

The most widespread is the notion according to which cyber security is identified with information security, which refers to protection of information and information systems against being broken into, used, spread, or subjected to service interruptions, unauthorized changes, or destruction, with the aim of guaranteeing their confidentiality, integrity, and availability. The emphasis in information security is put on preventing unauthorized access to information systems. From this standpoint, confidentiality of information is the main consideration.

According to another, newer, approach, the term *cyber security* is identified with the term *information assurance* (IA). IA is defined by the National Security Agency of the United States as a number of measures for protecting and defending information and information systems by means of securing and assuring their availability, integrity, authentication, privacy, and nonrepudiation. It includes measures for backing up a system, its protection, detection that the system is being hacked, and reaction to attacks. Assurance represents the level of confidence that is proportional to the efficiency of additional measures of security. The introduction of this term, in a way, testifies to the change of the granite concept of security, typical for traditional information systems that were not connected to a network, toward a more flexible concept of security that on one hand, implies that the nature of cyberspace is against reaching absolute security and, on the other hand, is measured by the value of information and devices that have to be protected.

Information Characteristics

The progress in computer technology and ways of interconnecting computer systems has, thus, widened a list of information characteristics upon which security requests are put, regarding the concept of IA. From the point of view of information assurance, it is of great importance to fulfill the following information characteristics (or information security services and information systems): privacy or confidentiality, integrity, and availability.

Confidentiality of information can be related to national security (e.g., information about weapons), industrial security (e.g., projects relating to a new product), or the personal privacy of a user. Integrity aspires to ensure that information and resources commanding it (hardware and software) can be modified and destroyed only with a special and formerly defined authorization.

The aim of availability is to ensure that information and services related to it are at any moment available to authorized users. In other words, a system that offers such services has to function only when it is requested to, and in a limited and already scheduled time. From the operational standpoint, availability refers to acceptable system response time and appropriate quality of service. From the point of view of information security, however, availability means the ability to protect from a damaging event or the possibility of system backup in cases when the damaging event has already taken place. Availability of modern information systems, which are in a state of ceaseless activity, is required not only for regular activities of an information society but also for safety of human lives (it is enough to mention, for example, the systems that control air traffic or automated devices in an operating room).

Authentication is a measure of security with the aim to determine values and validity of transfer and message of sender. This measure also controls authorization of a user to receive specific categories of information.

Nonrepudiation is a measure of security with the aim to ensure the stream of communication. It makes sure that the sender of information has proof of its delivery, but at the same time, that the receiver has the information about the identity of the sender, so that none of the participants in the process of information transfer can later deny that the transaction was performed.

The level of importance of the mentioned information characteristics, from the security point of view, varies depending on the context in which information exchange takes place. In military systems, for example, confidentiality of information is of vital importance, wheras in financial transactions among banks, the emphasis is on integrity.

A Complex System

Cyber security cannot be separated from a general context in which an information society operates. It encompasses a wide range of activities and measures and thus represents a complex system, bearing in mind that it unites various but, at the same time, equally important aspects. That means that none of them can be neglected: if one part of the system received less attention, the whole system would stop functioning correctly. Such complexity makes it difficult to achieve an absolute level of security. It is not possible to eliminate completely a risk from inadequate, accidental, or deliberate use of instruments of the information era. Cyber security is, thus, above all, achieving control over the risk, continuously searching for a compromise among the value of what has to be protected, the level of protection, and the price of protection.

Achieving cyber security at a supranational level requires the synergic activity of all subjects of the international community, with a primary role for experts in the field of information sciences. Preventive activities for adopting hardware and software standards, establishing national and supranational expert bodies, improving international cooperation in this area, and adjusting national laws in the field of cyber crime are essential steps for improving security of cyberspace.

The need to develop concepts of "cyber security," on an international level, is especially highlighted in the Declaration of Principles, which was adopted by the World Summit on the Information Society in 2003. In the chapter of the declaration dedicated to building confidence and security in the use of ICTs, it is stated that for the development of an information society and creating confidence among the users of ICTs, it is necessary to strengthen mutual confidence, as well as information and security of computer networks, authentication, privacy, and protection of users. A need for promotion, development, and implementation of a global culture of cyber security through cooperation of all decision makers and international expert bodies is stressed. This effort should be supported by improving international cooperation. Within a global culture of cyber security, it is important to improve security and ensure protection of data and privacy of users, together with improving the possibility of access and trade. These activities, according to the declaration, must take into consideration the social and economic level of each country, as well as respect development-oriented aspects of information society.

Cyber Warfare

The security of highly information-based societies, which in all their segments depend on computers and computer networks, can be jeopardized not only by physical threats but also by threats from cyberspace. That is why cyber attacks, in all technologically advanced countries, are perceived as one of the greatest threats to national security, and securing one's own national cyberspace is considered to be an absolute imperative. Cyber warfare is a particular and comparatively new form of social conflict. Activities of cyber warfare usually reduce to offensive use of cyber attacks, as well as taking measures of precaution and using tools for prevention of breaking into one's own systems. The main characteristic of this kind of conflict is that it takes place in cyberspace by means of software tools and propaganda techniques, as well as various techniques for deceiving an opponent's use of information-communication technologies, with the aim of causing damage to the opponent, his or her information infrastructures, and other mutually interconnected critical infrastructures, as well as the data contained in them. Although it takes place in a virtual world, cyber warfare can result in real material losses and human casualties if targets of those attacks are, for example, critical infrastructures or supervisory control and data acquisition (SCADA) systems for automated control of industrial processes. Cyber warfare can be waged independently or as a support to a conventional, kinetic conflict.

The Unique Nature of Cyber Warfare

Cyber warfare is, according to most of its characteristics and principles, different from conventional, kinetic warfare. One of the basic differences lies in the nature of their environments. Kinetic warfare takes place in a physical world and is governed by the laws of physics. Cyber warfare takes place in an artificial world that can hardly be predicted and is susceptible to quick changes. That is why only a few principles of kinetic warfare can be implemented in cyber warfare.

The term *cyber warfare* originates from the military discourse and is frequently identified with *information warfare*. That kind of identification is not completely justified because cyber warfare is only a variation of information warfare—the former term covers a narrower range of uses because it limits activities of information warfare to the space of computer networks. Today, many countries and their armies are developing doctrines and strategies of offensive and defensive cyber warfare and forming special units for performing information combat. In that regard, for example, as of October 2010, the U.S. National Cyber Security Strategy had been officially approved, and in the same year, the United Kingdom government announced a new national security strategy in which cyber warfare and terrorism were proclaimed the greatest threats to the country. During the North Atlantic Treaty Organization (NATO) summit in Lisbon in 2010, a new strategic concept of this organization was adopted. Among the most important aims, which should be realized by 2020, there is protection from unconventional threats, that is, updating the approach of the alliance for solving crises caused by such threats as terrorism, proliferation of the weapons of mass destruction, cyber attacks, and disruption of vital energy streams of supply. Article 12 says that cyber attacks have become more and more frequent, organized, and expensive from the aspect of the damage they cause to governments, businesses, economies, and, potentially, energy transport and supply, as well as other critical infrastructure. They pose a threat to the national and Euro-Atlantic security, stability, and development. Today, the term *cyber warfare* is used not only to describe military offensive and defensive activities in cyberspace but also as an umbrella term for denouncing a wide range of activities on individual, social, and corporate levels that are usually subsumed under cyber crime.

Actors of cyber warfare are numerable—they can be national armies, security and intelligence agencies, politically and ideologically motivated individuals, "hacktivists," various formal and informal subversive social groups (terrorists, criminals, and religious sects), and also business corporations competing against rivals for domination of the market. Sides in the conflict try to use any kind of system vulnerability or weakness (technical or human) of the victim. The arsenal of cyber warfare is very diverse and numerous—attacks are usually performed by means of malicious software (malware: virus, worm, Trojan horse, backdoor, spyware, keylogger, hijacker) and compromised computer networks (botnet) with the aim of causing a distributed attack targeted at service obstruction (distributed denial-of-service-attack (DDoS). In addition, in order to obtain administrator authorizations and other necessary information for initializing an attack, phishing techniques and social engineering are used. As objects of cyber warfare, data and information in electronic form, computer systems, and critical information infrastructure in general, can be identified.

Although activities of cyber warfare have been carried out for over a decade, an adequate legal definition for them still has not been found. The entire field of cyber law is still not properly developed. Some attempts at applying already existing models from international laws of war to this area have been shown to be inappropriate. Moreover, a general consensus on international agreements that would clarify the legal status of state and nonstate actors in cyber conflicts has not been reached.

Taking into consideration the lack of consensus regarding formal and legal ownership over the Internet, existence of national and regional developing disparities regarding approach to information-communication technologies, and the globally present battle for domination in cyberspace, a tendency of activity growth in the field of cyber warfare can be expected in the future, especially bearing in mind that the number of users of the global network is continuously growing while prices of computers, computer equipment, and software are falling. That makes the tools of cyber warfare widely available to all potential actors of cyber conflicts.

Damage Assessment

Assessment of disaster impacts is crucial to the many different aspects of response, recovery, and mitigation activities occurring post disaster. Not only must damage assessments be completed in a timely fashion for initial responders and search-and-rescue (SAR) teams, but they must also accurately quantify both areal extent and level (limited to catastrophic) of the disaster impact for higher-level decision making, long-term response planning, and recovery operations. Imprecise damage assessments can have dire consequences at all levels of disaster response and management. The criticality of damage assessments to U.S. disaster operations is evidenced in the Homeland Security Geospatial Concept of Operations. Damage assessments supported by location-based technologies such as geographic information systems (GIS), global positioning systems (GPS), and remote sensing (RS) are recognized as crucial missions and provide important components of the essential elements of information (EEIs), which inform decision-making processes during initial response and recovery operations and influence longer-term rebuilding and mitigation efforts. Incomplete or inaccurate assessments may slow the procurement and delivery of assets to the affected area and can lead to complex or complicated disaster events that sometimes result in even more devastating impacts in the long run. Damage assessments are part of routine emergency operations at the local level, but assessments for larger events that surpass local capabilities are not regularly trained for or undertaken in a standardized fashion from place to place. Different methods, achieved using disparate means and yielding divergent results, were not uncommon until very recently, when automated procedures began replacing flawed computations and human introduction of error and bias. This technologic innovation, although welcomed and useful, does not completely replace human intellect within the disaster decision-making process but rather provides a rapidly deployable additional resource to the emergency manager's arsenal.

History and Methods of Damage Assessment

The concept of understanding disaster impacts is not a new one. Chronicles of disasters, their damage to landscapes, and their effect on people can be found as far back as 9,000 years or more in old African cave etchings revealing details about prehistoric flood events. More detailed maps depicting spatial locations of disaster impacts can be traced back to both the 1854 London cholera outbreak and the devastating Japanese earthquake and tidal wave. Throughout human history, people have (for pragmatic reasons) become ever-entwined with disastrous places and subsequently have felt the impacts of hazard events. Lack of sufficient details on the scope and spectrum of a disaster's impact can have dire consequences for the entire disaster management cycle. Vast improvements in technology, communication, visualization, and spatial understanding have occurred since the first known "damage assessments," yet the premise of understanding the consequences of disaster remains constant. Comprehensive damage assessments that balance speed with the provisioning of adequate details are necessary for both short- and long-term response planning and operations. Decisions about which response assets to utilize during the initial phases of response are inextricably linked to understanding the impacts on individuals and communities in a disaster area. In the longer run, return and recovery can be managed more succinctly if plans are made based upon quality base (damage assessment) information.

Historically, a number of different types of damage assessment and varied methods for capturing, analyzing, and understanding damages across space have been invented, improved upon, and in some instances mandated as part of a larger emergency management process. Generally, these assessments fall into three main categories, each linked with the scale of disaster: initial damage assessment (IDA), preliminary damage assessment (PDA), and technical damage assessment (TDA). During every emergency event from a routine traffic accident to a major disaster occurrence, an IDA is conducted. Here, local emergency response personnel reconnoiter the area and begin mobilizing local and regional resources through memorandums of understanding (MOU).

Often, these IDAs are termed "back of the envelope" because they are routinely undertaken with both the greatest of haste and with resources at hand (i.e., back of an available envelope). IDAs are often completed by conducting a drive-through assessment where officials scour the area for a general understanding of the damages. If the disaster is large enough to overtax local resources (flooding, hurricanes, chemical spills, etc.) a preliminary damage assessment (PDA) is undertaken. Here, a more complete and fact-based (empirical) assessment of damages takes place that results in a tally of damages (both financial and from a volumetric standpoint) to buildings, businesses, infrastructure, and residents. Often, ancillary impact/damage data such as information from nonprofits (Red Cross and other volunteer organizations), hospitals, and the general public is included in PDAs. This type of assessment generally includes the use of aircraft so that officials can understand and estimate the scope of damages from a broad perspective. The PDA is a required step in the process of requesting a presidential disaster declaration (PDD) both in the United States and across the globe. Because the PDD is the means by which the federal government justifies and allocates financial and other disaster support assets to an area, the PDA must not only be accurate and complete but must also be undertaken rapidly. The final type of damage assessment—the technical damage assessment—involves very specific insurance and federal investigation into both the site-specific (house, critical infrastructure piece) causal agent of damage and a strict economic accounting of damages, losses, and costs of the disaster. The TDA is used both to identify appropriate reimbursement amounts and to plan operations for the often long road to recovery from disaster.

The Future of Damage Assessment

Until very recently, all of these types of assessments were completed and compiled by hand and used less-than-perfect technologies coupled with imprecise analysis where human bias was consistently introduced. Although the "first" people may have simply been telling a story about a specific event, such actions have evolved over time to include the most sensitive remote sensing technologies. A new advent of practice-oriented (rather than research-based) supercomputing is enabling real-time, on-the-fly damage assessment using remotely sensed imagery. Included in this ever-evolving science are three main advancements in the creation and utilization of remote sensing technologies. First, the sheer number of available "vehicles" for capturing remotely sensed imagery of the Earth is greater now than ever before. There were four times the number of satellites capable of capturing information about the Earth's surface launched into orbit around the Earth in 2011 than there were just 10 years ago (Figure 1). Although each of these has its own specific mission and capabilities, the fact

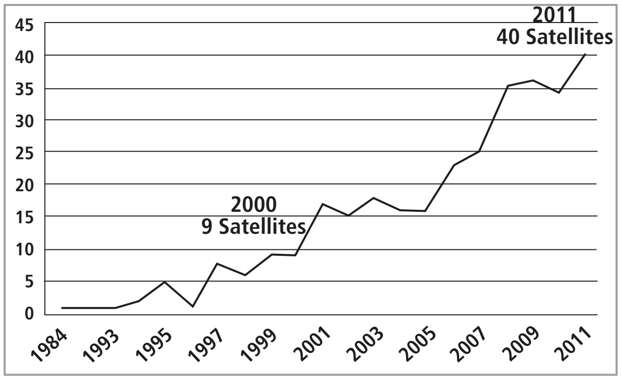

Figure 1 Total number of observational satellites launched since 1984

Source: Union of Concerned Scientists Satellite Database, 2012.

that more than 950 (known) observational satellites currently orbit the Earth helps us understand the sheer volume of Earth surface data being collected and analyzed across the globe.

Couple these with emerging capabilities related to local remote sensing using portable/unmanned sounding or imaging devices and the number of available assets in a post-disaster environment becomes countless. Utilizing unmanned aerial vehicles for the capture of remote sensing imagery and spatial data is perhaps the best example of this ever-evolving scientific field. Researchers have already begun the tenuous process of vetting this new technique and have identified numerous applications, including rapid deployment into hurricane impact areas where historical remotely sensed damage assessments have often taken days to collect and weeks to process into usable spatial data for decision making.

Applications of this technology have a lower cost, a more flexible ability to deploy assets, and a less time-intensive turnaround on final data products. However, although the cost of this new technology is lower than traditional in-flight data collection, it is not without cost. For this reason and the fact that the United States, other global governments, and private-sector partners have already deployed assets capable of the same data collection, there are other opportunities to access remotely sensed damage assessment data at little or no cost for disaster response activities. Numerous efforts are under way to speed access to useful remotely sensed data pertaining to crisis response. Among these is the International Charter–Space and Major Disasters (www.disasterscharter.org), which aims to provide a unified system of space data acquisition to mitigate the effects of disasters on human life and property. Additionally, the Remote Sensing Hazard Guidance System (RSHGS) (ww2.rshgs.sc.edu) developed through Department of Homeland Security Science & Technology (DHS S&T)–funded research at the University of South Carolina is a Web-based decision support tool supporting hazards managers in the process of acquisition and analysis of remotely sensed imagery for their area of interest.

RSHGS provides information on satellite resources and capabilities—an invaluable tool for incident commanders; however, under many disaster scenarios, satellite-based resources are not usable because of weather or atmospheric disturbances, creating more opportunities for the deployment and utilization of manned and unmanned aircraft. Although planners, emergency managers, and decision makers can now quickly identify informational needs about a hazard area quickly and accurately—both requisite characteristics of damage assessment needs—challenges still remain in provisioning these aerial assets in a timely manner. To be effective for life-saving missions, RS data and imagery-derived products must reach the frontline responders within 12 hours, and derived damage assessment products must be in the hands of community assistance and recovery teams within 48 hours to effectively support delivery of community rebuilding processes and aid critical sector restoration activities.

Missing Pieces and Opportunities

The sum of all the technology across the globe cannot make up for the fact that disaster/crisis events are often unanticipated and impact areas of the globe where residents are less than prepared. Couple this with the fact that we currently do not have a complete understanding of the true costs of disasters in the United States and around the world, and one quickly realizes that each piece of the emergency management puzzle is just as important as the others. Effective and efficient emergency response and long-term recovery may be in part based on quality damage assessments, but the process of creating replete damage assessments must begin long before the disaster event. Pre-impact planning based on efficacy in every aspect of emergency management provides the basis for quality response and recovery efforts in which complete IDAs, PDAs, and TDAs are made possible through unified multiple data collection, analysis, and assessment. Unity of knowledge, or consilience, across disciplines, sectors, agencies, and the general public, coupled with information about losses from a central loss repository, will enable responders and decision makers to understand past and future damages, calibrate models, and create new techniques—not simply for damage assessment but also for the larger community of responders, emergency personnel, and citizens.

Formal incorporation of location-based technologies into the emergency management life cycle is a prerequisite for developing a culture of preparedness that sees location-based technology as a necessary component for ensuring that the right information gets to the right people at the right time. This delivery of real-time information and data informs our understanding of crisis events, producing better decisions, and the routine testing of these capabilities creates a culture of preparedness and a technical state of readiness for sustaining life-saving, damage assessment, and recovery and mitigation missions.

Damage Containment

Damage containment—often referred to as "damage control" or just "containment"— is identified by most emergency management researchers as the most often overlooked aspect of emergency planning. Planning for damage containment is as an element of mitigation and actually occurs in two stages. The first stage is in planning for future disasters, and the second is in responding to an event.

Planning for Damage Containment

Each situation presents a different paradigm of planning for damage containment. In the case where a new structure is being planned, the concept of damage containment can be applied in site selection. There are obvious things that should be considered: selecting areas outside established floodplains; avoiding building on slopes of hills where tall grass, brush, or timber may dry and a fire develop (fires tend to naturally climb hillsides); building in high-crime areas; and other considerations particular to the facility being built.

Once a suitable site is selected, planning for damage containment should continue in determining materials and design; a bank and a cardboard box factory require different levels of design and structure. Structures can be designed specifically to resist earthquakes, wind (even tornados and hurricanes), fire, and flooding. Different levels of security as well as fire suppression can be designed into the building. Installing redundancies into systems is a way of lessening the damage that can occur in a system loss. The level of security and safety that can be built in is determined mainly by the budget available for building.

Some buildings are designed to accomplish damage containment by keeping the danger confined to a specific area. Some are designed to prevent fire from spreading from one area to another. Nuclear power plants are designed to be locked down and sealed to prevent the escape of radioactive materials.

Damage containment usually refers to an attempt to confine damage to a certain level within a certain area. The *Titanic* was deemed unsinkable, not because of special hull strength, but because of the use of bulkheads that were designed to contain any flooding that might occur. Ships

Case Study: Chernobyl—Planning and Response Damage Containment

On April 26, 1986, in Chernobyl, Ukraine, which was then a part of the Soviet Union, the world watched a major nuclear disaster play out through the obscured lens of Soviet secrecy. The Chernobyl nuclear power plant suffered an explosion and fire that released huge quantities of radioactive materials into the environment. The accident was caused by an electrical power failure that resulted in a loss of necessary water transfer to keep the radioactive materials at a controlled temperature.

Nuclear power plants are designed with thick concrete and steel housing intended to contain radioactive materials, even in the event of an accident, provided there is sufficient water exchange to keep the temperature within certain parameters. Tests had revealed a flaw in the backup electrical plans, resulting in a power gap that would allow the radioactive materials to super-heat.

The actual cause of the disaster was explosion and fire, but it was most assuredly a series of events and failures that led to the single greatest nuclear accident in history. One of the major contributors to the destruction was the Soviet practice of keeping secrets even from their own people. Instead of evacuating the nearby towns, there was no discussion about the accident itself, and assurances were given that all was normal. Responders were not given the needed information to make a proper response, so containment efforts of firefighters proved fruitless.

In the post-Soviet days, more has been learned about the event. Evidence indicates that poor planning and design of the nuclear facility led to ineffective containment barriers. The roof of the facility was not constructed according to design specifications, which allowed radioactive materials to escape as a result of the explosion and fire. The uncontained explosion threw large pieces of graphite fuel rod channels out of the facility and onto responding firefighters and emergency response personnel; these materials were extremely radioactive. The firefighters and other emergency personnel had not been properly trained to respond to a nuclear explosion and fire, nor were they equipped to protect themselves from the radiation.

The containment effort continued until May 10, 1986, when the fire was eventually extinguished in the reactor core. This was accomplished through a massive effort that involved using helicopters to drop 5,000 metric tons of materials onto the burning reactor itself. The materials included boron (which absorbs neutrons), clay, sand, and lead. In addition to the material that was air-dropped, responders pumped liquid nitrogen directly into the reactor.

Nuclear material was spread over a rather large area, but fallout spread across a huge region of the Soviet Union and eastern Europe. Estimates have placed the potential death toll at more than 200,000 persons, but whatever the number, the incident continues to claim victims through deaths resulting from radioactivity-induced cancers.

Chernobyl represents a model of what goes wrong with poor planning in design and response, coupled with ineffective response measures.

The Chernobyl power plant reactor number 5 sits ghostlike in October 2011, 25 years after an explosion and fire caused the single greatest nuclear accident in history. The event also became a prime example of nearly everything that can go wrong within planning, design, response, and damage containment. The design of the facility led to ineffective containment barriers, emergency personnel had not been properly trained for or protected against a nuclear accident, and the Soviet government withheld critical information.

and submarines are still designed with watertight bulkheads designed to be closed to contain flooding or fire to a specific area. Damage containment can also be accomplished through designs to keep hazards from entering; a double-hulled ship is an attempt to confine the damage to the exterior skin and not allow water into the larger body of the ship.

Some buildings are designed to accomplish damage containment by preventing external hazards from entering the building; these buildings can shutter themselves to prevent toxic fumes and poison gases from entering. This is damage containment through design to restrict hazards from entering buildings. Schools, hospitals, and residence care facilities are the most common structures of this design. The building has the capability of being completely sealed, augmented by positive internal pressures. The air supply is recirculated through cleansing filters designed to detect toxic and poisonous substances.

Another form of planning for damage containment can be accomplished through segregation of assets; this is referred to in risk management as "spreading risks." One of the more common mistakes in discussing the concept of spreading risks is to confuse the term with "sharing risks," which is the use of insurance. Spreading risks literally means putting assets in different locations so that no one event can destroy everything. This recalls the adage "don't put all your eggs in one basket." In investment planning, a common strategy is to spread money across different opportunities to avoid one failure causing a total loss of assets; the same concept applies here. Damage containment through spreading became more popular following the events of September 11, 2001.

Many of these provisions may be viewed as costly, but nothing saves response and damage costs more than preventing an event altogether. If an event cannot be totally prevented, lessening the damage is the next most advantageous attempt. Properly planning for damage containment can pay for itself many times over in stopping one event. Prevention of an event is the ultimate damage containment.

Damage Containment Through Response

Obviously, the best of plans are sometimes foiled by acts of nature, human failure, or intentional design. Should an event occur, adequately planning and equipping for a response is the next stage of damage containment. Auxiliary equipment can be installed to provide advanced damage containment, but properly trained personnel can enhance the cause further. Installing advanced firefighting equipment and emergency medical devices (such as portable automatic defibrillators) can help defer damage, but having employees trained to operate the equipment properly adds to the level of protection. The training and prevention programs may be augmented further through the employment of practice drills and exercises. These exercises should be coordinated with response agencies to allow for verification of correct addressing of alarms and 911 call systems; an incorrect auto-address assignment can be easily discovered in a coordinated exercise, but left undiscovered can become an element of disaster.

In a response, damage containment often requires resourceful thinking and innovative response measures. The very nature of damage containment during response means that the situation is not under control, and this tends to be a very-high-risk period of the response. Once damage containment features are in place, the response will shift to extinguishing the event completely; this is true of all disasters, whether human-made or natural.

One of the more memorable attempts to bring a disaster under control during the response phase is the Chernobyl nuclear reactor accident of 1986, but there are examples of damage control in response for every disaster.

Damage Containment Methods

There are a variety of methods for accomplishing damage containment during a disaster response. These include utilizing specially designed materials and devices, such as oil containment booms, petroleum-eating bacteria, spill-absorbent materials, temporary liquid barriers, and new innovations that are being introduced all the time. During the BP Gulf of Mexico oil disaster of 2010, specially designed ships were deployed that collect oil-contaminated water and clean it through a filtration system, retaining the oil for refining and returning the water to the ocean.

Damage containment methods for forest and grassland firefighting can include removing potential fuel sources to create a fire break, applying fire retardant materials to block the path of the fire by denying it fuel, and reverse burning to cause a small controlled fire to move against the larger uncontrolled one to remove fuel and oxygen from the larger fire.

Almost every disaster has some methodology designed to help contain damage and bring the disaster under control.

Psychological Damage Containment

A growing form of damage containment is psychological damage control—working to prevent long-term mental health issues in victims and responders alike. Psychologists are increasingly finding evidence of post-traumatic stress disorder in victims of natural and human-made disasters. Once thought to be a product of battlefield action only, its recognition in victims quickly led to acceptance that responders also suffer from the disorder.

Many response agencies now offer psychological counseling and stress debriefing exercises for both victims of and responders to natural and human-made disasters. Here again, this works best with preplanning and special training. Research indicates that responders are more likely to participate in post-event counseling and debriefing exercises when these are made a part of their training programs.

Conclusion

Damage containment saves lives, property, and money. Effective damage containment is a product of proper planning, design, and the equipping and training of personnel. Perhaps the most important aspect of damage containment is to encourage innovation in the methods used to bring an event under control.

Dams, Levees, and Seawalls

Dams, levees, and seawalls are all barriers against water. A dam blocks the flow of water for the purpose of impounding it, generally storing it in a reservoir, sometimes with the additional benefit of yielding hydroelectric power. Levees manage water flow and redirect it away from protected land regions, such as the settlements around a body of water; they either occur naturally or are constructed, usually parallel to the course of a river, but sometimes following the shore of some other body of water. (The word originated in New Orleans, Louisiana, where levees are constructed around Lake Pontchartrain.) Similarly, seawalls are constructed around the coast to reduce coastal erosion and protect habitats and human settlements from wave and tidal water.

Seawalls

Seawalls are expensive to construct but provide a more long-term solution to coastal management than does maintenance of beaches. In many locations, a choice must be made—constructing a seawall often requires destroying the beach. Furthermore, wheras a seawall can be constructed to protect inland habitats, it can also destroy shoreline habitats, many of which—such as wetlands and intertidal beaches—are especially fragile and key to the planet's biodiversity. Seawalls that replace beaches also jeopardize recreational tourism and quality of life for locals. The conventional wisdom is that although beaches provide some protection from coastal events—they form a buffer between the shore area and inhabited areas—seawalls do a much better job of minimizing property damage and hazards to human life in extreme events like tsunamis or hurricanes. This wisdom has been challenged by recent events. Forty percent of Japan's coastline was lined with seawalls and similar structures when the 2011 Tohoku earthquake and tsunami struck, damaging the containment buildings of the Fukushima nuclear power plant. These seawalls were a key component of postwar Japan's initiative to introduce nationwide infrastructure that provides a rigorous defense against earthquakes and tsunamis.

However, reliance on the seawalls to do their work may have allowed standards to be more lax in other areas of building than if the seawalls were not there. Fukushima's diesel generators, which powered reactor cooling systems during shutdown, were positioned on the assumption that the coastal seawalls would prevent flooding. They did not—waves rushed over the seawalls. At least some of the damage at Fukushima would have been preventable had more of the plant been designed with the possibility of a seawall failure in mind. As many critics have pointed out since the tsunami, the efficacy of seawalls is hard to quantify because the extreme events that put them to the test happen so rarely.

Levees

Like seawalls, levees primarily protect land areas from water. The levee system in New Orleans has often presented problems. During the Great Mississippi Flood of 1927, when the Mississippi basin was hit by heavy rains and the rivers swelled to record levels, 30 tons of dynamite were detonated on the levee at Caernavon, Louisiana, during a torrential rainstorm in order to keep the levees around New Orleans from spilling over. New Orleans escaped serious damage, but neighboring St. Bernard and Plaquemines Parishes (counties) were significantly flooded. It was thought to be a fairly clear-cut case of poor black neighborhoods being sacrificed in order to spare rich white ones, and the same charge was levied against the involved governments in 2005 following the failure of the levee system during Hurricane Katrina, which disproportionately affected black neighborhoods. There is no evidence of a conspiracy in that more recent case; the rumors of such simply evince the poor state of the levees. Their failure was responsible for more of the damage in New Orleans proper than the hurricane wrought directly. Both independent investigations and the Army Corps of Engineers' own reports showed that the levee failure resulted from a faulty design. The natural forces exerted on the levees were well within the limits of what the levees were intended to withstand; a National Science Foundation investigation found evidence that the Corps was aware of these design flaws no later than 1986. As with the Japanese seawalls, one of the problems with a levee system is the choices that are made on the assumption that it will work; in this case, the existence of the levee system almost surely influenced the delay in calling for a mandatory evacuation and may have influenced the choices of some of those who chose to stay, when weighing the expense of departure. It undoubtedly also influenced design choices made in the city, and the city and Orleans Parish's choices in budgeting for and designing disaster protection plans, since the maintenance of the levee system had been assumed by the Corps and its efficacy was treated as a fait accompli.

Dams

Dams, on the other hand, generally are built not to protect from disaster but to control water level, whether the principal aim is to maintain a reservoir, generate hydroelectric power, or limit water flow in order to render land habitable. A dam failure is a catastrophic event, enough so that in times of war, the laws of armed conflict forbid the targeting of dams in inhabited areas. Prior to the adoption of this law, the British Royal Air Force targeted three German dams in World War II's Operation Chastise, in order to hurt Germany's infrastructure and manufacturing capacity. Dam failures can be caused by natural disasters, erosion, or geological instability, but often the cause is anthropogenic: the 1972 Buffalo Creek flood in West Virginia killed 125 people as a result of design failure four days after its satisfactory inspection; the 1985 Val di Stava dam collapse killed 268 when negligent maintenance allowed sediment to build up and warp a drainage pipe; and in 1889, the South Fork Dam in Pennsylvania failed because of a poorly designed spillway. The resulting flood of Johnstown was the first major disaster relieved by the newly formed American Red Cross.

Data Mirroring

As individuals, organizations, government entities, and corporations prepare to deal with potential disasters and crises that may arise, data mirroring has come to represent increasingly important practices, policies, and procedures for these groups. Data mirroring involves the replication of data stored on logical disk volumes on separate physical hard disks, often in real time, so that continuous availability of that data is ensured. Data mirroring provides several advantages in crisis management situations, insofar as it protects data in the event of hardware failure, but it also significantly improves system performance with regard to speed. More sophisticated systems of data mirroring permit data backup to occur while the first disk remains active.

Storage Replication

In the event of a disaster, either natural or human-induced, having the information technology (IT) systems that support a business or organization secure is of vital importance. Since the 1970s, when business leaders first began to understand the increasing importance that constant access to data meant to their organizations, interest has developed in providing a safe and reliable means to safeguard data. Beginning in the late 1970s, companies such as Sun Information Systems (later known as SunGard Data Systems) began providing backup computer systems that would preserve a client's data in the event of a disaster. Such endeavors provided what is known as hot site/cold site locations. A hot site is fully equipped to permit an organization to resume operations after a disaster; a cold site does not have that capacity but does preserve data that would otherwise be lost. Organizations that preserved their data at hot or cold sites made a cost-benefit analysis that assisted them in deciding what sort of backup arrangements were needed. These determinations are made as part of the development of a disaster recovery plan.

Disaster recovery plans focus on various control mechanisms that can assist in reducing or eliminating various threats to an organization's operations. Disaster recovery plans are generally a subset of an organization's continuity planning. As such, disaster recovery plans need to include planning for resumption of applications, communications, data, hardware, and other IT infrastructure. In the event of a major crisis or disaster, plans to replace personnel and facilities and to augment communication must also be considered. Strong disaster recovery plans consider three aspects: preventive measures, detective measures, and corrective measures. Preventive measures include those steps that are taken to prevent an event from occurring, such as precluding flood damage or power outages. Detective measures involve using controls to detect or discover unwanted events, such as monitoring systems for computer viruses or hacking. Corrective measures are those that involve restoring the system after a disaster so that operations may resume in a timely manner.

When considering an appropriate disaster recovery plan, organizations must consider appropriate recovery point objectives (RPOs) and recovery time objectives (RTOs). An RPO involves the maximum tolerable period in which data may be lost from an IT service because of a crisis. RPOs provide system operators a guideline for planning for backup services; for example, if the RPO were set at six hours, daily backup would be inappropriate. An RTO represents the duration of time in which a certain process must be restored after a disaster or other interruption of service. RTOs generally include time to fix the problem, the recovery itself, testing, and communication of the problem to users, as well as a return to full service. Data mirroring is a means of providing continual backup of data, thus permitting an RPO of zero lost data.

Data Mirroring

Storage technology that employs multiple disk drives to achieve data mirroring is sometimes referred to as "redundant array of independent disks" (RAID). RAID is a method of storage virtualization, a means of providing very fast and very reliable data storage. First developed at the University of California, Berkeley, by David Patterson, Garth A. Gibson, and Randy Katz in 1987, RAID was soon marketed commercially as a means of providing quick and safe data protection. Originally, there were five RAID levels, each of which indicated basic RAID configurations, each with relative benefits and failure rates. Data mirroring is generally synonymous with RAID 1.

Disks are an inherently unreliable component of computer systems, with the average disk having a 5 percent probability of failing within five years. To remedy this, RAID 1 creates an exact mirror (or copy) of data on two separate sets of disks, which do not have to be housed at the same location, thereby increasing the reliability of the data storage. This setup is most useful when read performance, or reliability, is more important than data storage; as such, an array can only be as large as the smaller of the two member disks. Because each disk contains a complete copy of the data and can be read independently, reliability of the system is raised by the power of the number of self-contained copies. If only one disk fails, no data are lost. Although a RAID 1 system provides effective protection against physical disk failure, it is not effective in combating computer viruses, accidental file changes, or deletions. To provide better protection against such harm, any data mirroring system must also be combined with a robust backup system. Some systems store a series of backups so that inappropriate changes can be fixed if needed. Remote backup services are often used to prevent the loss of data in the event of a disaster. Continuous data protection systems allow a system to immediately log every change on the host system; it differs from data mirroring in that it allows a rollback of the log.

Mirroring may take place locally, where it specifically protects against disk unreliability, or it may be done remotely. When mirroring takes place remotely, it generally forms part of a more sophisticated disaster recovery system. Certain data mirroring systems combine both local and remote mirroring, usually to protect high-availability systems that have a large volume of users. Data are usually mirrored onto a physically identical drive, although sometimes the process is applied to logical drives that are different, as the fundamental physical format is hidden from the mirroring process. Although data mirroring was initially a hardware solution using disk arrays, it now also can use software within the operating system. Several possibilities exist when a disk fails. In a hot swap system, the system itself diagnoses a disk failure and signals the system administrators. If the system is sophisticated enough, it automatically sets in motion a hot standby disk and utilizes the functioning active disk to copy live data to this disk. Failing this, a new disk is installed immediately to replace the failed disk, and data are copied onto this disk. In less advanced systems, the system operates on the remaining disk until a spare disk can be installed with minimum disturbance. Some data mirroring systems utilize three or more disks, with two of the disks used for the redundancy mirroring and the third disk utilized for backups. The third disk is sometimes referred to as a business continuance volume (BCV).

When data are copied from one disk of a mirror to another, the process is sometimes called “resilvering,” which is a rebuilding of the data. During the resilvering process, system performance is interrupted or significantly degraded, as the disk system is fully occupied in the process of copying data from the remaining disk to another. Mirroring of disks must be augmented by regular backups. Although many organizations utilize frequent and comprehensive data backups, this is especially important for commercial entities, as user mistakes, processing errors, and hacking are not protected by data mirroring. Rapid data links, such as those provided by fiber-optic links, allow data mirroring to take place site to site, especially if the distance is 1,500 feet or less. For remote data mirroring, asynchronous copying systems are often used.

In addition to preserving additional copies of data, mirroring allows separate disks to be accessed individually for reading purposes. Many large organizations maintain multiple mirrors for this purpose, because in the case of a disaster or other crisis, several tasks may compete for data on the same disk. Data mirroring permits faster downloads of data accessed via the Internet, and many corporate and other organizational users utilize mirrors dispersed geographically to improve performance. Data mirroring also helps organizations to balance the load on their servers, which can be helpful if a disaster strikes and causes an upsurge in usage in a certain region.

Data Recovery

The purpose of data recovery is to create and maintain the ability to recover data that are required to perform one or more necessary functions. Prior to designing data recovery, the functions must be prioritized and the required data identified. Recovery objectives are defined, including the recovery time objective (RTO) and the recovery point objective (RPO). The RTO is the length of time a function can operate without the data, and the RPO is how old the data should be when they are recovered. After these recovery data requirements and recovery objectives are determined, processes are put in place to back up and recover the required data meeting the recovery objectives. After all the processes are in place for backup and recovery, those processes are tested regularly to ensure they will work properly when needed. Data recovery is an activity that is authorized by the crisis management process.

Business Impact Analysis

Necessary functions are identified using a business impact analysis (BIA) or a similar tool for nonbusiness purposes. The BIA lists the functions performed and prioritizes them in order of most important to least important. Another determination is the RTO for each function; usually, the more important the function, the shorter the RTO. Then the RPO is determined by understanding the maximum age of the data that must be recovered. At times, functions cannot continue if they must start again with recovered data that are too old. This also helps determine the backup and restoration processes that must be used. Typically, the shorter the RTO and smaller the RPO, the more expensive data recovery will be.

Along with the BIA are financials that state the various costs of all functions not working. Quantifying how much revenue will be lost or how much cost will be incurred while waiting for the data to be recovered helps tell how much to spend on the data recovery processes. Typically, the higher priority a function has, the more it will cost in revenue or other costs to be without the function. Conversely, functions with a low priority typically don't garner much revenue or cost much to be without for extended periods of time. Of course, when this information is presented, it is up to the highest-level decision makers to determine how much they are willing to spend on data recovery to mitigate the identified costs. With an approved spending threshold, the data recovery processes can be determined. At times, the data cannot be recovered within the approved spend threshold. If that happens, the decision makers must decide whether they want longer RTO and RPO to avoid the cost of data recovery or provide additional funding to accomplish proper data recovery.

Armed with the entire set of requirements and objectives from the BIA and the spending threshold, the data recovery processes can be designed. The first part to design is the data backup. Longer RTOs and RPOs allow less expensive backup and recovery designs, while shorter RTOs and RPOs require more expensive backup and recovery designs. The data must be backed up in a format that can be recovered according to the RTOs and RPOs.

Recovery Objectives

Very short RTOs and RPOs make it necessary to design a high-availability (HA) environment where data are used or stored in two geographically separate locations at the same time. HA environments allow either location to be destroyed with little to no loss of data and little to no recovery time. Of course, the people performing the function must also be HA so that the entire staff is not disabled with the single location. Short RTOs and RPOs provide some leeway in design. There are backup processes called "replication" that back up data from one location to another, called a hot site, with dedicated equipment ready to be used. When the original location goes down, the replicated site can come online in the amount of time it takes to bring the systems up using the replicated data. Data recovery can take from minutes to hours.

Medium RTOs and RPOs allow backup and recovery of more moderate expense. Knowing the amount of data to be recovered helps as well. Many backup and recovery options have estimates of backup and restore data transfer speeds. This means it is possible estimate the amount of time it will take to back up and also to restore the data during recovery. For example, if the data transfer rate is 3 billion characters per minute and the data to restore amount to 300 billion characters, then the restore will take about 100 minutes.

If the data transfer speed meets the RTOs and RPOs, the design will work well for the recovery. When designing for data recovery in the medium RTO and RPO range, a warm site can be used. A warm site is an alternate location with equipment in several different states of readiness. Some equipment is powered off, waiting to be used, and other equipment is powered up and ready for use, as well as leaving space for equipment that can be shipped for longer RTOs and RPOs. In many cases faster tape backup and restore devices are used, allowing recovery in one or more days.

Longer RTOs and RPOs offer even more choices. A cold site is an alternate location with no powered up equipment—often just an empty shell of air-conditioned, raised floor space. The use of a cold site is the least expensive choice, other than doing nothing, but again, it requires RTOs and RPOs of days or longer. The option of preconfigured equipment shipped quickly to the cold site can provide an affordable recovery option. Again, often tape backup and restore media are used, and even slower, less expensive devices can be obtained. Another option is to recreate systems from the install and either reenter data or start fresh, entering older data by hand as time permits.

Bunkers

One final option is to avoid losing data and also avoid having the cost of equipment just for recovery. One choice that meets these criteria is known as a bunker. Just as the U.S. military used bunkers to protect assets, a business can use a bunker to house its existing systems and data. Because the bunker is impervious to all natural hazards and most human-made hazards, there is only the need for the equipment used on a daily basis. No extra cost for backup equipment for alternate site recovery is needed, no HA site, no cold site, no warm site. The only drawback is that everyone must access the site through network connections that may go down; but redundant connections and redundant telecom vendors in the site can allow a quick switchover to an alternate network vendor.

Backup Media

Some other things to consider are the different forms of backup media. There are two major types of backup media: optical and magnetic (electronic). The possible environmental threats that the backup media would be exposed to should help determine which media are used. Optical media tend to be stored on reflective material in a plastic substrate, such as compact discs (CDs) and digital video discs (DVDs). These optical media are susceptible to damage from scratches, heat, and ultraviolet rays from the sun over prolonged exposure. Magnetic media such as tapes and external hard disk drives (HDD) are susceptible to electric surges and strong magnetic fields as well as string X-rays that may be found in airport baggage scanners.

Whichever backup media are used, there should be periodic backups to acquire several versions of information just in case one medium is destroyed or cannot be recovered properly. There are several types of periodic backups using media. Often, there will be a full backup once a week or once a month followed by daily incremental backups. Incremental backups hold only the small amount of information that changed that day. Recovery would first need to restore the full backup to get all the information and then apply incremental backups to bring the data to their most current state.

Older media backups should be kept track of so they can be destroyed or converted as newer media replace older media. Some media backups should be stored off-site to protect them from harm during disasters. There are many off-site storage vendors that even have climate-controlled storage rooms to prevent condensation from forming within the media containers and damaging the media.

Conclusion

One of the activities that can be authorized by crisis management is data recovery. The purpose of data recovery is to create and maintain the ability to recover data that are required to perform one or more necessary functions. To design a good recovery, there must be a business impact analysis that prioritizes each function, identifies the required data, and determines both the RTO and RPO. Once the requirements and priorities are set and agreed to by decision makers, a cost threshold for the design is determined and the design is conducted using standard recovery options such as hot sites, warm sites, and cold sites or bunkers. After design approval, the design is implemented and then tested regularly to ensure it will work properly when needed.

Debriefing

Crisis managers understand that the damage does not end with the event; for instance, the effects of the September 11, 2001, terror attacks are still being discovered and evaluated. One very important post-event component of crisis management is the debriefing, or post-crisis analysis. Debriefing exercises usually are conducted shortly after the event, and sometimes again after participants have had the opportunity to rest and refresh themselves from the event, which allows reflection time. A debriefing exercise has multiple purposes, depending on how it is structured, and with proper planning can be beneficial in many ways. These include experiential learning, event reconstruction and investigation, screening for post-traumatic stress disorder (PTSD) and other mental health issues, public confidence building, and research.

Experiential Learning

Debriefing and post-crisis analysis are used in experiential learning. Debriefing individuals involved in a crisis event, whether as victim, respondent, or nonparticipating witness, leads to information that helps in the development of training and education for future events. In this type of debriefing, the questions center on words like who, what, where, when, why, and how. The purpose is to collect experiences within the framework of understanding what happened, what things could have been done to lessen the impact of the event, and how to avoid or prepare for future events.

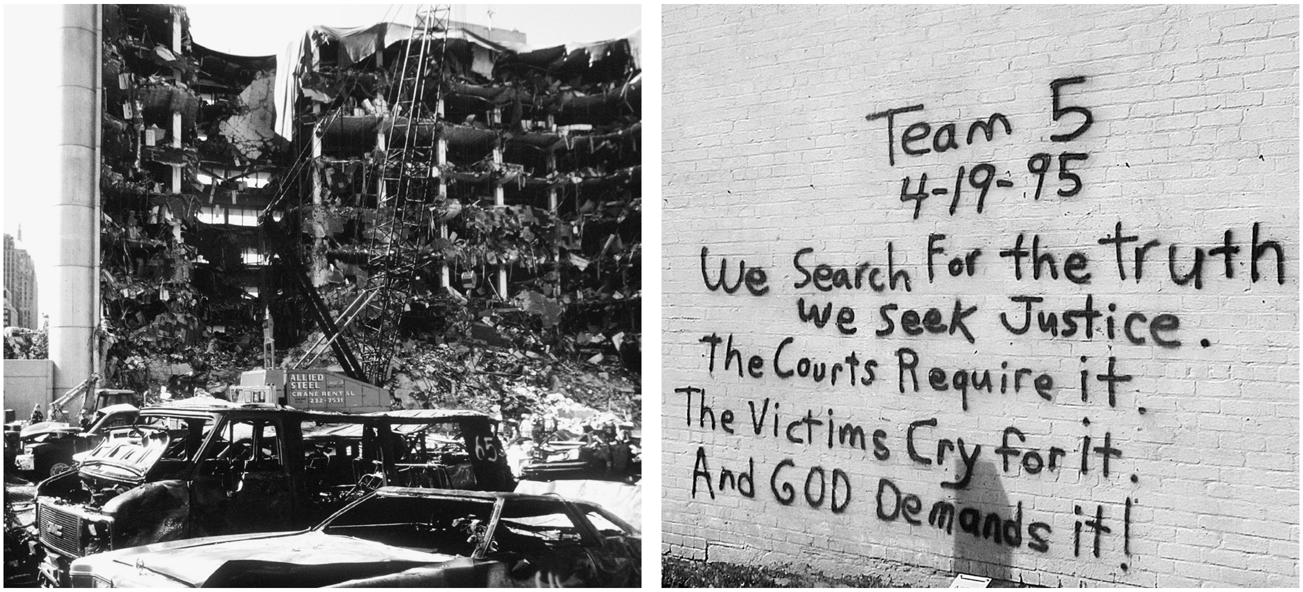
Post-crisis analysis may go beyond debriefing to include a review of archival information, such as newspaper reports of the event, photographs of the event and of the affected area before and after the event occurred, post-event maps, weather and geological data from the time of the event, official reports, and even the diaries of persons involved. Depending on the age of the event, there may also be an attempt to collect archaeological and anthropological information, such as has been done in the study of early and prehistorical events.

The findings are used to assist planners in developing more informed responses to future crises of a similar kind, if not in the same location. Trainers use the information to revise or design new programs or to develop practical exercises and drills, to inform the public about protective measures, and to help responders prepare for future crises. Educators use the information to develop course curricula for developing emergency managers.

Experiential learning can also occur immediately, using a debriefing session following the critical incident. Generally, because of the need for expediency, the session is a very basic discussion between those involved about what happened, what caused the event, how the crisis played out, and who did what during the event. As participants tell their stories, the facilitation can develop a discussion about how the response could have been improved; the purpose in these sessions is not to belittle or ridicule but to collectively learn a better approach to future incidents, or even how to avoid a similar event altogether.

Event Reconstruction and Investigation

Debriefing for event reconstruction and investigation has been done since before recorded history; investigators seek to put the stages of an event into an order that can be understood and give meaning to the specifics being reviewed. The desire to investigate and determine what happened in the



The charred hulls of automobiles remain in front of the bombed Alfred P. Murrah Federal Building in Oklahoma City two days after a car bomb exploded inside the building on April 19, 1995 (left). Rescue Team 5 spray-painted a message (right) on a brick wall nearby in the aftermath of bombing. This was a sentiment echoed during the post-crisis analysis and debriefing process, which helped investigators to reconstruct the attack, determine the cause, and identify a suspect.

process and cause of an event (post-crisis analysis) is a natural human instinct.

In modern times, new investigative abilities have improved post-crisis analysis. The process of reconstructing critical events has been greatly improved with the development of computer-aided design (CAD) and other digital imaging advancements. Using eyewitness accounts, known data, and digital imaging and design, investigators can reconstruct the crisis event and explain the multiple causes of an event. Having the ability to input known data to determine if it fits into the models developed from debriefing helps investigators know where to look for more clues. As an example, the multiple causes of the sinking of the *Titanic* are becoming clearer with the help of the ability to observe the debris and enhance computer modeling.

Information from post-crisis analysis (investigation) and reconstruction helps investigators not only to determine the causation but also to develop suspects in cases where the crisis appears to be a criminal or terrorist event. Post-crisis analysis, including information obtained from debriefing eyewitnesses and physical evidence, helped investigators to reconstruct the devastating attack on the Alfred P. Murrah Building in Oklahoma City in 1995 and to demonstrate the plausibility of the single device explosion.

Screening for Mental Health Issues

Counselors use debriefing of victims, responders, and eyewitnesses in post-crisis analysis to identify emotional welfare concerns. The debriefing is the second-level contact with persons directly involved in a crisis event, the first being "defusing." Defusing is often confused with debriefing, but it occurs immediately following a crisis event, at the scene, and is essentially an outreach to explain the normalcy of the feelings being experienced, and to provide a communications lifeline for access before the debriefing occurs.

Emotional welfare debriefing usually occurs within hours of a critical incident. Depending on the situation, the debriefing may be done individually, one-on-one with a counselor, or in a series of group sessions; the determination of method is based on the type and scope of the event. The International Critical Incident Stress Foundation (ICISF) has established guidelines for conducting debriefing of this kind. The ICISF debriefing process follows seven steps: The intervener introduces self, establishes guidelines, and invites participants to introduce themselves, making clear that participation is voluntary (although attendance itself may be required); details of the event are developed from individual perspectives; emotional responses are given subjectively; discussions look at personal reaction and actions; this is followed again by a discussion of symptoms exhibited since the event; there is an instructional phase where the team discusses the symptoms and assures participants that most are a normal reaction to an abnormal event and that these should diminish with time; and this is followed by a brief period of shared informal discussion, most often done in a relaxed atmosphere, often with nonalcoholic drinks and snacks. The participants are then allowed to return to duty and resume normal tasks. Throughout the ICISF process, the intervener is attempting to identify individuals who are not coping well; these participants are offered additional assistance. This debriefing process is usually followed by intervener visits with participants; again the purpose is to ensure that proper coping patterns are being followed.

Unfortunately, there is some evidence from research that indicates that critical incident stress management itself has little benefit for victims, responders, and witnesses of critical incidents. However, there is also evidence that the debriefing itself, the talking about the incident, allows participants to identify with each other and develop self-help networking.

Public Confidence Building

Debriefing is a method of building public confidence in the ability to address issues of crisis management and response. In this form, those conducting the debriefing collect the stories and evidence relating to the critical event. The information is analyzed by the government or responsible organization to identify those practices that worked well, those that need improvement/alteration, and failures that can be attributed elsewhere. The focus is to use debriefing exercises to demonstrate concern for the public and environment through pre-event preparation, planning, and training; interest in the welfare of the general public and responders; and dedication to being better prepared for future events. Classic corporate examples of using the debriefing process in this way can be found in the *Exxon Valdez* and British Petroleum Gulf oil spills.

One side benefit of this paradigm of debriefing is that the organization learns firsthand and early what those involved will be repeating to news media and in other public forums, allowing for “damage control.” A second side benefit is that the organization can develop an understanding of any health issues (physical and/or mental) that may be forthcoming as a result of the event. Another benefit is that the organization can use the debriefing process to demonstrate concern to the affected persons.

Although this form of debriefing for damage control may seem questionable, these are common practices for both government and private organizations and have proven effective in reducing the impact of an event on them.

Research

Post–critical event debriefing works well for qualitative research into the various stages of a critical incident. The researcher has a distinct advantage in being a part of the debriefing team but can also benefit from recordings and documents collected during debriefings when the researcher is not a part of the team. There are lessons to be learned, and benefits to research activities, from debriefing sessions conducted for all of the other purposes. In conducting research into the crisis event, the investigator develops themes that correlate across the observations and stories from the participants. These themes can be explored further against the backdrop of the physical evidence available, or the information can be developed solely as experiential.

In this kind of research, the investigator may answer questions about perceptions of surviving the critical event, which training related to the response to the critical event, and many similar questions. There are many cases where such research was not the motivation of investigator involvement in the debriefing, but as the information collected was processed, themes developed that led to deeper understanding and/or new knowledge of benefit to others.

Post-Crisis Analysis Separate From Debriefing

There are many aspects of post-crisis analysis that are distinguished from debriefing, and the post-event analysis can continue for many years beyond the event itself. Such an example is the Chernobyl nuclear plant disaster that occurred in 1986. Although the debriefing phase is long past, the post-crisis analysis continues. Data collected immediately following the event and during the response are being analyzed in new ways to develop deeper understandings of what went wrong, how the response could have been more effective, and what the long-term effects are to human life and the environment.

Another excellent example is the *Columbia* space shuttle explosion that scattered debris over east Texas and west Louisiana in 2003. The National Aeronautics and Space Administration (NASA) is still collecting and analyzing debris from that critical event. There have been repeated studies done on locals in the area to determine health, particularly focusing on increases in cancer rates of people living in the debris field and those responding to the cleanup/collection effort.

Such post-crisis analysis can include field research as well as testing in a laboratory. In this form of analysis, highly specialized technicians and investigators seek to determine causation in an effort to avoid future events.

Conclusion

Debriefing is a part of post-crisis analysis but plays the central role in reviewing a crisis event. This is because the debriefing process includes participants who were victims, responders, and witnesses to what occurred. Even in recent times, investigators are going back and reading the papers, diaries, and texts of interviews with *Titanic* survivors. The stories, drawings, and observations reanalyzed provided new insight into what happened in this tragedy of passenger shipping. Some of this information has led to new theories about the ship's underwater resting place, and the evidence collected from the scene of the debris field has yielded new clues. Some of the evidence has shown that early statements of survivors about what they saw, once dismissed as confusion, are now supported by debris findings.

Debriefing and post-crisis analysis play an important role in the emotional healing process and future mental health of those involved in a crisis event. Another important contribution is to the improved knowledge of how to prevent and better respond to crises. Debriefing can serve many different functions in the post-crisis period.

Debris Management

Debris management is a critical but understudied phase in disaster response and recovery. Indeed, of the top 10 most expensive disaster recoveries in United States history (measured in terms of federal relief funds expended), six occurred in the last 10 years—and all were debris-inducing events. Debris management refers to the process of planning for, removing, and disposing of debris induced by disasters.

- Pre-event planning consists of activities associated with identification of debris removal capacity in at-risk areas, as well as forecasting of debris fields and estimation of personnel and equipment requirements
- Debris removal consists of activities associated with identifying and removing debris from public (and sometimes private) land and waterways

- Debris disposal consists of recycling, destroying, or otherwise disposing of debris that has been removed

In all of the above phases, advanced technologies are increasingly being used to support (and sometimes substitute for) debris management activities accomplished by debris management personnel. As has been amply documented elsewhere, large-scale debris-inducing events continue to pose considerable challenges for efficient, effective, and equitable debris management activities.

This article reviews the major phases of debris management, with particular emphasis on current practices and likely future challenges.

Pre-Event Planning

Pre-event planning encompasses three activities: advance contracting, temporary debris storage and reduction (TDSR) site screening and selection, and debris field forecasting and estimation. Advance contracting identifies a single contractor responsible for debris removal in a specific area. This contractor is then responsible for contracting and managing any debris mission in its region. TDSR site screening is used to identify geographic areas that are appropriate for temporary storage of debris. Debris field forecasting and estimation occurs in the days or weeks before a debris-inducing event in order to estimate resulting volume, distribution, and composition of debris. Forecasting models are often embedded in computer-based tools used to guide decisions about initial activation of debris removal personnel and equipment.

Debris Removal and Disposal

The debris field may consists of a potentially wide variety of material distributed over the landscape. Debris is typically cleared from property and roadways and pushed to curbside, where it is segregated and loaded onto trucks and trailers at designated pickup points by debris removal teams. Loads are then delivered by truck to temporary debris storage and reduction sites (TDSRs), and their size estimated. Highly distributed teamwork is central to the organization of the debris removal mission.

The three broad stages of debris removal are identification, pickup, and reduction. Concurrent with activities in these stages are monitoring and reporting of field conditions. Debris pickup may have several subphases, including a first pass to open main arteries for emergency vehicles, clearance of rights-of-way such as secondary roadways, and clearance of debris from private property. In the United States, debris removal from waterways is likely to require coordination of organizations such as the U.S. Coast Guard. At some point, the debris removal operation is declared to be completed. Key measures of performance effectiveness are likely to include incremental (e.g., daily) and overall volume/weightage of debris removed, as well as progress in reducing the volume of debris at TDSRs. To support the debris removal mission, new techniques and technologies have been developed for tracking debris loads and estimating their size. These may range from small, handheld devices that function much like bar code scanners to more sophisticated technologies that will "X-ray" the contents of the hauling vehicle.

Debris disposal activities include recycling, burying, or burning various types of debris, both nonhazardous and hazardous, as appropriate. Given the volumes that may be generated by large-scale events, as well as difficulties in segregating materials in the debris stream, recycling continues to pose a challenge to debris management. Similarly, affected areas may be limited—due to environmental and other regulations—in their ability to burn or bury some types of debris.

Conclusion

Recent disasters such as Hurricane Katrina in the United States in 2005 and the 2011 earthquake, tsunami, and nuclear "triple disaster" in Japan have highlighted debris management challenges associated with scale, scope, and type of debris. In the coming years, debris management is expected to become more integrated into the overall emergency management cycle. Indeed, efforts are under way, both in the United States and abroad, to revisit long-standing practices in debris management, whether in the development of guidelines for best practices or in the development of new technologies.

Debt Crisis

A debt crisis occurs when borrowers' margins of safety have eroded to the point where borrowers are unable to meet their scheduled debt obligations and risk a default without intervention. Although the term generally refers to macroeconomic, nation-state actors, global financial organizations have long been involved in debt crises, and the underlying phenomena may also apply to individual actors.

Typologies of Crisis

More broadly, a crisis is a type of social change where individuals, organizations, and society face widespread exceptions over a relatively short duration. Crises often serve as focusing events for media, the public, and policy makers to pay attention to a certain problem and to attempt to resolve the problem through some sort of collective action. Thus, a key component of a crisis is the relatively short duration when the exception occurs, media and the public pay attention, and policy makers are willing to dedicate time and resources to attempt to resolve the problem. Within economics, a crisis is commonly referred to as a dramatic and painful deviation from a well-established norm.

Over the past three centuries, a variety of economists, philosophers, sociologists, political scientists, and policy makers have offered various typologies of crises related to debt. Many of these typologies have highlighted banking panics, stock market crashes, financial bubbles, currency crises, and sovereign defaults as separate types of debt crises. Perhaps the most notable of these individuals was Karl Marx, who argued that capitalism was the first system in human history where overproduction was possible. Once overproduction occurred, Marx reasoned that it can set in motion a vicious cycle of reactions leading to falling profits, investment declines, increased debt, unemployment, and deflation. For Marx, a crisis did not result in the collapse of the capitalist system, but rather enabled the system to survive periods of fluctuation through increased consolidation, ultimately making the system more unstable in the long run.

More recently, scholars from the 1960s onward have sought to conceptualize what is a crisis, identify crisis symptoms, and attempt to offer integrated solutions, or at least attempts to ease crises for those most vulnerable. During this period, one of the more influential of these "crisis theorists" was James O'Connor, whose work sought to identify crisis tendencies in capitalism and the increased consolidation and integration of private and state actors in contemporary capitalism. O'Connor was among the first to argue that as the private sector runs into debt crises, the state must play an increasing role in resolving these problems. As the state becomes increasingly involved in the capital system, profits tend to be privatized, while economic risk tends to be disproportionately borne by the state. An additional important aspect of this analysis is that nearly every social group wants resources from the state, but few, if any, groups want additional taxes, creating a gap between revenues and expenditures, known as the fiscal crisis of the state. This fiscal crisis of the state tends to lead to other forms of social crisis. O'Connor's work heavily influenced the social philosopher Jurgen Habermas. Habermas offered a highly influential view of crisis as a systemic problem in capitalism resulting from "steering problems" between economic, political, and sociocultural actors. Over time, these unresolved steering problems may lead to economic crisis, rationality crisis, legitimation crisis, and motivation crisis.

More recently, economic scholars Carmen Reinhart and Kenneth Rogoff have conducted empirical analyses of economic downturns across centuries and concluded that that there are five "varieties" of financial crises: external default, domestic default, banking crises, currency crashes, and inflation outbursts. Although all of these financial crises are useful for comparison between crises over time, all of these typologies and categories are largely symptoms of debt crises rather than exploring the mechanisms that are similar across all types of financial crises.

Debt Crises and Financial Instability

Building upon prior research on debt and finance by Joseph Schumpeter and John Maynard Keynes, the economist Hyman Minsky offered an alternative approach that could more adequately explain the origins of instability and the importance of debt in understanding crisis. In Minsky's view, social organizations create an evolutionary process of invention, innovation, and obligations. For each unit, whether a household, a firm, or a national economy, these obligations appear as liabilities on the balance sheet and determine a series of prior, current, and future obligations that constrain or facilitate future opportunities. Because investment and debt obligations play a central role in understanding the financial system, banking, in the broadest sense of the term, including bank intermediaries, offers a useful starting point for understanding the overall workings of the capitalist system.

For Minsky, the debt-income relations of finance break down into three ordinal categories from stable to fragile. First, "hedge finance units" are those that can fulfill all payment obligations with their cash flows. The greater the income relative to debt on the balance sheet, the more stable the financial unit, and the greater the number of hedge finance units in the financial system, then the more stable the financial system. Second, "speculative finance units" are those that can meet their payment commitments on income accounts even though they cannot repay the principal with their cash flow and, consequently, must roll over their debt obligations at specified times. In this instance, when a firm recently purchases a new capital good and can make regular payments but cannot pay off the asset all at once, the firm is said to be a speculative financial unit, as debt on the capital good must be rolled over at a specified interval, whether it be at the end of a month, quarter, or year. Because a bank would be relatively inefficient if all of its cash flows exceeded its debt, or amount loaned, most banks fall into the category of speculative financial units. Third, "Ponzi finance units" are those whose cash flows are not sufficient to fulfill either repayment of the principal or the interest due on outstanding debts from cash flows. In this instance, Ponzi units can either sell assets or borrow additionally to meet prior debt obligations; however, a unit engaged in Ponzi finance lowers the margins of safety it offers to holders of its debt obligations. It is important to note that Ponzi finance does not necessarily mean the financial arrangements of an institution are fraudulent or deviant—it simply indicates that this type of borrowing may not be sustainable in the long term and these financial arrangements are more susceptible to market conditions, such as increases in wage or construction costs or increases in interest rates or short-term market fluctuations. Generally, the greater the number of speculative and Ponzi finance units in the system, then the more fragile the financial system.

The financial instability hypothesis begins with the proposition that in the capitalist economy, finance occurs within a system of borrowing and lending based upon the "margins of safety," or the ratio of cash flows relative to debt obligations. When hedge finance units dominate the economy, there is general stability in the financial system. Over time, speculative or Ponzi finance units may offer innovations not traditionally found among hedge finance units. Because innovation is an essential aspect of the capitalist economy, hedge finance units may invest in the development of instruments and markets that enable higher levels of profit to be financed. In return, borrowing units assure those who finance them that the money will be available at the appropriate time requested. This success of prior hedge investments into speculative and Ponzi finance units breeds confidence, additional borrowing, and additional economic expansion. During this period of economic expansion, additional borrowing tends to result in a decline in hedge finance units and an increase in speculative and Ponzi finance units.

Over time, this period of economic expansion may lead to economic euphoria and a belief that a new era has arrived, where increasing short-term financing of long positions becomes normative.

Once an investment boom starts, the volume of funds demanded increases and the rapid expansion of investment straps “liquidity,” or the amount of capital available to be borrowed. During this period, debt-to-equity increases, margins of safety erode, and a generalized belief may emerge that these developments are not cause for concern. The reason for this is that as innovations gain increasing acceptance, output, employment, and firm profits increase, leading many economists, financial experts, and policy makers to believe that hedge finance units were justified in their decision to invest in financial innovations. This period may also be characterized by a disregard for the possibility of failure, and in the absence of serious failure, this leads to further support of the exuberant economy. During this exuberant period, warnings that there is a financial breaking point that will lead to a crisis are ignored because of such profitable circumstances. Additionally, because critics may not have quantitative data to support future predictions that differ so drastically from the contemporary reality, their claims and unconventional wisdom are easily dismissed and ignored by the established authorities of economics, finance, and policy.

However, delays or unforeseen exceptions lead to additional unanticipated erosions of the margins of safety. When these unanticipated erosions occur, additional borrowing is required, or firms may engage in balance sheet adventuring to avoid disclosing their actual exposure to risk. Once this occurs, speculative and Ponzi units, debt laden and reliant upon borrowing to meet current obligations, must attempt to shore up their financial positions and may have difficulty doing so as additional questions may arise about their financial stability. The two most frequent sources of unanticipated erosions of the margins of safety stem from the long gestation of capital-intensive projects and financial innovations that fail to produce the projected levels of output. The financing of positions may also be complicated whenever short- and long-term interest rates rise, and new valuations must occur. In an effort to shore up financial positions, more stable hedge and speculative units may request additional capital from borrowing units. Speculative borrowing and Ponzi finance units, which are entirely reliant upon the servicing or sale of debt to meet current obligations, must use their margins of safety, which may quickly disappear once selling of liabilities evaporates and short-term financing is still necessary to meet current obligations. Because Ponzi finance routinely results in a continuous erosion of equity, Ponzi financial units may no longer become rare and the financial system becomes increasingly fragile as the ratio of Ponzi finance units increases. As an increasing number of units are unable to meet debt obligations, firms may attempt to merge, be acquired by other financial units, or request lender of last resort action from the federal government.

Finally, at this point, a break in the boom occurs, leading to a debt crisis, or as is more commonly reported, economic or financial crisis. The extent to which the financial system will enter a recession or depression depends largely upon the overall liquidity relative to government policy and lender of last resort actions by the government. Lender of last resort interventions almost always follow an explosion of speculative and Ponzi finance, and generally, once a lender of last resort intervention has occurred, hedge finance units, burned by their previous speculative or Ponzi finance investments, build up their margins of safety once again, to the point where the cycle may repeat.

Decision Making

One of the most important responsibilities a leader has is the power of decision making. Especially during a crisis, the ability to make decisions becomes extremely important and essential for leaders and responders. Decision making can be defined as the process a person goes through in order to make the choices he or she needs during a crisis. This skill can be one of the most important skills a leader has in a crisis situation and is often one of the first things followers or team members will look to as a quality for their leader.

With all of the stresses brought to a crisis situation, the ability to make decisions becomes harder because of the additional burdens resulting from what has happened. A crisis will bring time pressures, risks, and an ever-changing situation, and seldom will the crisis responder be able to control the timetable of the event. The people who make the decisions in the crisis will have to make many difficult decisions and will ultimately be responsible for those decisions once the situation has calmed down. Often, the decision makers will express self-doubt, lose their own perceptions of the scenario, or cause stress upon themselves about the decisions that were made in the heat of the crisis.

It is important that when decisions are made, they are made quickly and decisively. The first consideration should be people's safety, and the decisions that are made need to be communicated precisely to those who need the information. Frequently, the decisions will need to be made quickly with little or no information available, but it will be the responsibility of the crisis leaders to do their best to make the most informed decisions they can as rapidly as possible. Most decisions will not be easy to make and may even be based upon conflicting information. These decisions will need to be prioritized in importance and communicated appropriately.

Making a Decision

When a decision needs to be made, it is best to make the most informed decision possible. The decision maker will need to decide what the desired outcome will be and design multiple choices to try and attain that outcome. In order to make the best decision, it will be important to utilize data and documents, other team members, and experts' opinions to decide which of the choices will be best. Rules, regulations, and policies will need to be considered and weighed into the decision-making process. After examining all of the possible factors, the decision maker will need to make a choice between the different choices created in order to achieve the outcome.

During a crisis, time will often be a major factor in the decision-making process. Time must be accounted for by the decision makers, and at some point a decision must be made in order to move on. It is important that clear communication channels and access to resources have been established before the incident in order that a timely and correct decision can be made during the actual crisis.

Decisions Before the Crisis

One of the most important decisions to be made is to plan for the crisis before it happens. The decision to create a crisis management plan in advance, choose a crisis team, and practice scenarios in advance will give people the opportunity to become more aware of what crises they may face and allow them to practice sample decision making. During the actual crisis may not be the best time to think and second-guess decisions, so by thinking in advance about some of these decisions and their long-term outcomes, the decision maker may be better informed to make the necessary decisions.

During an actual crisis, the decision maker will often have only a short amount of time, with limited resources and information, to make the decisions he or she will need to make. With proper utilization of the training and preparation in the pre-crisis phase, the decision maker will become more skilled and aware of the right decisions he or she may have to make if an actual crisis were to happen.

Difficult Decisions

During a crisis, those who are responsible for making decisions will often have to make difficult decisions. This responsibility can be a heavy burden on some, and not everyone is willing to be placed into a situation where he or she will be accountable for decision making. The person making the decision will have to take responsibility for the outcome of those decisions. Because of this difficulty, the person making the decisions needs to make the most well-informed decision possible. This can be done by collecting information and data, talking with experts and counsel, not making assumptions, thinking about outcomes, and looking out for the safety of people and the protection of property.

Case Study: Decisions Made at Louisiana State University During Hurricanes Katrina and Rita

During Hurricanes Katrina and Rita, the campus of Louisiana State University was impacted not only by the damage caused by the storm but also by evacuees from New Orleans and other southern Louisiana towns. Operation of the university was disrupted, and administrators had to make many decisions regarding the sustainability of the institution and how to handle the institution's role in the crisis. Administrators at all levels had to make decisions regarding the operation of their particular units.

One of the important decisions that had to be made for the university was if and when the campus would reopen. The campus had suffered damage, athletic facilities now housed evacuees, parents and friends were living with students in their residence halls, other students and faculty had left town to avoid the storm, and many people throughout the city were still without power. Many staff and faculty members were volunteering in the relief effort and not doing their regular tasks. State and federal governmental agencies were on campus using facilities, and the military was a constant presence on campus. With all of the chaos on campus, administrators began to wonder if the university would ever reopen for normal business.

Administrators began to realize that if the university did not reopen shortly, the university would not be open for the semester, if not the year. It was decided that the university would open for classes on the eighth day after the hurricane. This was not an easy decision to make. University officials had to gather information and opinions from many people involved with running the institution. They had to make sure their facilities were operational, faculty and students could get back to the classrooms, and operations could return to normal. They looked at their options, knowing they would be questioned by many for returning to normal operations, which included everything from classes to athletic events. Some felt the university should remain closed in this time of crisis and continue with humanitarian efforts.

Additionally, a decision was made to open up the university to the University of New Orleans, another school within the system, so it could hold classes, along with admitting students from other New Orleans institutions that had to be shut down. Decisions were made to diverge from normal policy to enable the temporary admission of students from other universities for enrollment until their institutions returned to normal operation.

These were only two of the larger decisions that had to be made to restore operation of the university. During any crisis, many difficult decisions will have to be made. The outcome of those decisions may not be known until much later. At the time, many people thought the university reopening for normal operation was not the correct decision, and it was a hard one to make. However, time showed that the hard decision to reopen the university was the right choice.

Not everyone will agree with every decision that is made. Decisions will often be challenged, especially if they are controversial or if they have an impact on certain groups. Often, these challenges may come from those outside the organization, from groups such as stakeholders and the media. A well-informed decision-making process may be the best defense to any accusations. In the end, only in hindsight will people be able to know if the decision made was the right one.

Wrong Decisions

Even with much planning and forethought put into the decision-making process, wrong decisions will occur. With decisions being so crucial during a crisis, wrong decisions will often have a very drastic impact. Stakeholders and the media will often focus on the wrong decisions, even if there were very few, rather than concentrate on the correct decisions that were made. In the end, it is important for the crisis leaders and responders to take actions and make the decisions that will be needed, even if the decisions are later determined to be the wrong ones. Often, making a wrong decision will still be better than making no decision at all in a crisis.

When a wrong decision has been made and identified, the person who made the decision should be honest, apologize about the decision, and explain his or her decision-making process and how and why he or she made the wrong choice in that given situation. Once the decision maker recognizes that he or she has made the wrong decision, the decision maker should take the necessary steps to correct it. In some cases, it may be determined after the fact that it was the wrong decision, but it still would be in the best interest to explain that a mistake was made and proceed with taking whatever corrective measures may be necessary to right the wrong. Realizing one has made the wrong decision during a crisis is not the time to worry about one's own ego or the perception of others. It is best to admit the mistake that was made and to go about correcting this mistake.

Decisions for the Greater Good

One characteristic of decision making that is often expressed by those who have to make hard decisions during a crisis is to make a decision for the greater good. Often, during a crisis, decisions may need to be made that would go against the normal rules, regulations, and procedures one would follow during a normal situation. A decision may need to be made that would "bend" these regulations in order to do the greater good and protect or help the most people. In a crisis situation, ethical and moral responsibilities may override the rules and regulations that have been put into place to regulate day-to-day operations.

If a rule or regulation is broken when a decision is made to do the "right thing" and help people, one can hope that it will be judged to be the right decision in the best interest of people. That does not mean that a person would not be punished or reprimanded in some way for making the decision at that time.

Decision Making, Theories of

Decision making is the series of cognitive processes, by an individual or group, that selects an option—a choice or an opinion—from a set of possibilities. Formalized processes of decision making exist in a finite sphere—an election is a formalized decision-making process requiring candidates (the set of possibilities) to register and restricting such registration to a set defined by eligibility requirements, followed by a narrowing of the available options through the primary process, culminating in a vote that is then carried out by the electoral college and results in a binding choice. More simply, choosing an item for dinner from the menu is a process that exists in a finite period of time; the item is chosen, delivered, consumed, and paid for, and the process ends. But cognitively, decision making is a continuous process, a layer of the mind's interaction with the environment; the outcome of the election, or the taste of the meal we ordered, informs the choices we make next time. Regret, or opportunity loss, is the difference between the positive outcome we experience and the positive outcome we could have enjoyed if we made another choice, and some decision makers become motivated by attempting to avoid regret.

Decision making is affected by cognitive biases and emotional processes and may be rational or irrational, informed by tacit or explicit assumptions. Though much attention is paid to formalized, explicit, and therefore conscious decision making, most decision-making processes occur unconsciously—even when we are aware we are in the process, we rarely consciously examine the factors going into it or dwell much on why we may "just feel like it" when we make a particular choice like what to wear on a given day or what to eat for dinner. The mind's ability to engage in information-intensive decision-making processes without calling conscious attention to doing so, and without requiring the conscious engagement of the self, is an important adaptation—but it can lead to poor choices, which in crisis situations or for those in leadership positions is especially critical.

Decision theory is the study of decision making in terms of the rationality and optimality of the decision, and is pursued mainly in psychology and economics, especially with a prescriptive bent—that is, in the hope of identifying the best decision in a given situation, rather than descriptively analyzing the mechanisms of decision making without determining an optimum. Decision theory has a tendency to describe many decisions in textbook terms that are neater and tidier than what is found in the real world, and in this way differs from behavioral economics; decision theory will sometimes discuss binary decisions between two choices, like in the Prisoner's Dilemma or Pascal's Wager, which are rarely found in real life.

Although the ins and outs of decision theory overlap considerably with the modern science of game theory, many of its concepts originated much earlier, and the core concept of "expected value" was popularized by 17th-century French mathematician Blaise Pascal. In what is now called Pascal's Wager, Pascal described the relative outcomes of theistic and atheistic worldviews in terms of a decision, one that "bet" on a particular assumption (there is a God, or there is not) being correct. Decision theory now calls that scenario an example of choice under uncertainty, the class of scenario with which decision theory is principally occupied. Pascal's assumption was that the reward for theism was infinite if correct, and therefore belief in God was the pragmatic choice because disbelief offered no comparable reward; although the wager made many logical missteps and was founded on too many tacit assumptions to be useful to anyone in a genuine spiritual crisis, the framework of the argument was nevertheless compelling, and it anticipated elements of modern behavioral science that would not be explicitly formulated and identified for some time.

Causal Versus Evidential Decision Theories

Two opposing schools of thought in decision theory are causal decision theory and evidential decision theory. The causal school weighs the "expected utility" (a game theory term that replaced the older "moral expectation"—both terms refer to the positive outcome of a decision and its likelihood of occurrence) of an action in terms of that action's consequences. The evidential school weighs expected utility according to the best outcome that can be expected for the actor (the decision maker). The difference may sometimes seem negligible; what is key is the causal school's need for the actor's action to be the cause of the positive outcome. In the classic game theory example of the Prisoner's Dilemma—in which each of two individuals is told that if he betrays the other, he'll go free and the other will receive a long sentence, while if neither betrays the other, each will receive a short sentence—the causal school is unable to come to the same conclusion as the evidential school (that the actor should remain silent), because the actor's action is unable to influence the other actor's decision and so may be irrelevant to the outcome.

One of the concepts in decision theory that has a large impact on crisis decision making is ambiguity aversion or uncertainty aversion, a preference for known risks over unknown risks. Ambiguity aversion, for instance, is one of the factors that keeps people working at jobs they dislike, in relationships that don't make them sufficiently happy, or living in areas they know are unsafe—because while they know they are in a nonoptimal situation and have exposed themselves to a risk of negative outcome, they are also familiar with the situation and its risks, whereas a new situation would include many unknown elements. Risk aversion is similar but is specifically a preference to avoid risk even if that means limiting positive outcomes; ambiguity aversion prevents the actor from choosing options that may have very low risk, as long as the outcome is sufficiently ambiguous. Although women are more risk-averse than men, there is little gender difference in ambiguity aversion.

Another pitfall in decision making, especially in organizational decision making, is analysis paralysis, in which a decision is never made because the explicit decision-making process becomes overly detailed and cumbersome. Although individuals are prone to this as well, in organizations analysis paralysis can be the result of the need of an employee or executive to appear to be doing something, and when enough people are involved in the decision-making process, that can result in an overabundance of extraneous or overly granular information provided to the process, so that each person has a chance to make a contribution and tangibly demonstrate his or her involvement rather than simply register agreement with another person's input. Another way that analysis paralysis can occur is when every possible option includes the expectation of some amount of negative outcome. Rather than choose among negatives, no one is willing to appear to be supporting any negative outcome, and so decision makers circle around and around, unable to come to a decision that will minimize the negative outcome—or unable to do so in time for it to matter. In emergency management, there is a risk of this occurring when the situation is such that there is no choice that can be made that will solve everything; rather, priorities must be made, and decisions made accordingly. One of the main objectives of the professionalization of emergency management has been to avoid analysis paralysis in emergency management institutions.

Group decision making often leans toward consensus decision making, which bases its decisions on the consent of group members rather than on their agreement or on the advocates' ability to address objections to the decision. The goal of consensus decision making is to avoid adversarial decision making, so that there is no "winner" and "loser" in the process. Dissenters may have the option to formally declare their reservations or stand aside rather than block the decision.

Prospect Theory

Prospect theory is similar to decision theory but is descriptive rather than prescriptive and is part of behavioral economics. Prospect theory examines decisions actors make between options that involve a reasonably understood level of risk (rather than focusing on decisions made in conditions of uncertainty). Daniel Kahneman was awarded the Nobel Prize in Economics in 2002 for his work introducing prospect theory, which was originally described in terms of the decision-making processes involved in buying a lottery ticket.

Sense-Making and Situational Awareness

Sense-making is an important cognitive process involved in decision making. The term was coined in studies of human-computer interaction, but has been applied more broadly to the process by which people assign meaning to their experience–that is, "make sense" of it. Sense-making is the process of responding to the cognitive gap as the individual confronts observed data, especially when the individual is aware of an inadequacy in his or her understanding. In organizational science, sense-making is discussed as occurring on the organizational level rather than in the mind of the individual. Identity—who people think they are—is critical in organizational sense-making, which becomes a social activity as narratives are shared that could explain the data, with the most plausible narratives embraced by the group. Sense-making is increasingly recognized as a key process in understanding the cognitive processes of crisis management and critical decision making.

Situational awareness is another process that affects the information to which the actor has access in order to inform his or her decision. Situational awareness is the actor's perception and understanding of his or her surroundings, spatially and temporally, and of changing variables in those surroundings. It is often discussed in the context of emergency services, as police and firefighting personnel often arrive on a quickly changing scene with which they must engage; so, too, in the military and in aviation. Situational awareness can come from the actor's own perceptions or can be supplemented by information provided externally, such as being told where in a building a fire started, or on which floors people are known to be trapped, or by examining the building's blueprints. Sense-making is a process of engaging with data; situational awareness is the product of that process.

In contrast with decision theory, the naturalistic decision-making (NDM) movement began in 1989 to focus descriptively on the process of decision making rather than to analyze the optimal choice. Whereas decision theory weighs various approaches of decision making, NDM focuses on cognitive processes like situational awareness and sense-making, and the effects on the actor of factors like resource constraints, time constraints, high-stakes consequences, vagueness in specifying objectives, and the actor's experience level.

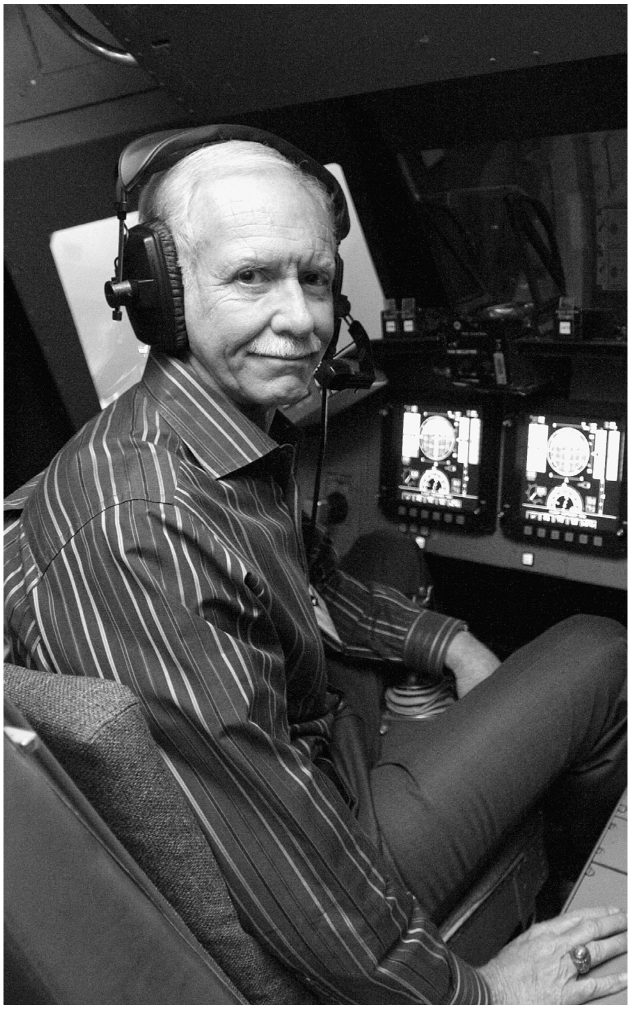
Decision Making Under Stress

Stress is one of the key factors that underlie the demands on decision makers when faced with crises. Whether the individual is an airline pilot; the manager of a nuclear plant; a police, fire, or naval commander; or an emergency or business continuity manager, crises are likely to result in decision makers dealing with an enormous number of variables, often in very short time frames.

Decisions are judgments or choices between two or more alternatives and include the period from the resolution of a problem to the implementation of a course of action. There are two comments to be made about this definition. First, one of those choices might be to do nothing, but it must be a positive decision to do nothing and not an abdication of responsibility. Second, in a crisis, there is no point in solving problems by making decisions if part of the process does not include the implementation of those decisions. Stress is the ordinary reaction of normal people to events that, for them, are unusual or abnormal. Invariably, decision makers will undergo some stress when dealing with crises. Increased stress can be both positive and negative. In some cases, it has been found to improve performance in that it makes people more alert and gives them an ability to think and act quicker; in other cases, heightened stress levels result in diminished performance.

Literature

Most of the literature on decision making is of little use to those who are required to respond to crises because it deals with the making of decisions in the normal progression of organizations. However, the most capable managers running organizations on a day-to-day basis are not necessarily those who will stand up best to the stress of managing crises. For instance, up until 1987, offshore installation managers—those in charge of oil rigs—were selected purely on their ability to get oil and gas from underneath the sea bed. However, in the inquiry into the Piper Alpha oil rig disaster, following a fire and its collapse into the North Sea and resulting in the deaths of 167 people, Lord Cullen, the inquiry chairman, found that the offshore installation manager (OIM) "took no initiative in an attempt to save life" and suggested that "the death toll of those who died ... was substantially greater than it would have been if such an initiative had been taken." Now, before being appointed as an OIM, a candidate is required to undergo simulated emergencies. It is essential that those who will be required to make decisions either at the strategic, tactical, or operational level are identified as able well before any such event.



Captain Chesley Burnett "Sully" Sullenberger III visits the virtual motion simulator at NASA's Ames Research Center, Moffett Field, California, December 15, 2012. Sully is best known for his cool-headed landing of U.S. Airways Flight 1549 in the Hudson River on January 15, 2009, saving all 155 lives on board.

The impact of stress on decision making can be significant and yet it is an aspect of human behavior that has, arguably, only been explored in the United States since it was mentioned as a factor during a congressional hearing in 1988 following the shooting down of an Iranian Airbus by the USS *Vincennes*, killing all 290 people on board. As a result, the Office of Naval Research sponsored a research and development program, Tactical Decision Making Under Stress (TADMUS), the aim of which was to provide principles and guidelines to enhance team tactical decision making in complex environments. At about the same time in the United Kingdom, Rhona Flin, a professor of psychology at Aberdeen University in Scotland, led a team looking at decision making under stress following the Piper Alpha disaster.

Causes of Stress

The causes of stress are many and varied. Crises produce unfamiliar and dynamic events; thus, they are constantly changing. Invariably, during the early stages, the scene or location of a crisis is confusing because information may be in short supply; later, the amount of information may be too much for the decision makers to absorb without support. Communication systems may have been destroyed or become inoperative. Resources may be in short supply or be inappropriate, and it may be necessary to coordinate the activities of numerous specialists, each of whom may have different vested interests. People may be seriously injured, even dead. There may be environmental factors such as the weather or the inaccessibility of the scene of the crisis.

The location of the decision makers may place them under additional stress if they themselves are in danger. A host of other people and groups are likely to put pressure on the decision makers, for example, senior management, who are concerned with the impact that the crisis will have overall on the organization; those below, who will be waiting for a decision to be made that decision makers may be incapable of making at that precise time because of a lack of information; the media, who have deadlines to meet; and the community, who are desperate to know how long the crisis will last and will it occur again. Finally, there is the time pressure. Time moves on, and this, in itself, puts pressure on decision makers, particularly if lives are at stake. All these place pressure on an individual's decision-making process.

Impact of Stress on Decision Making

A lack of training and a lack of experience coupled with a lack of ability or initiative leads to a lack of confidence and a fear of failure, thus placing decision makers under even more stress in already stressful situations. But it can also lead to a number of other negative aspects or defects in the decision-making process. For instance, tunnel vision or task fixation occurs because of a lack of knowledge of the type of crisis that has arisen; consequently, decision makers focus on what they know rather than on the wider picture. Alternatively, decision makers tend to focus on insignificant things that are, in relation to the actual crisis, often minor in terms of bringing the crisis under control. Because they are relatively immediate, decision makers may concentrate on short-term gains when under stress without thinking through the long-term implications. Alternatively, faced with serious crises arising from something they have done previously, or something they should have done that has been overlooked, the enormity of the situation suddenly hits them, and the resultant stress can cause them to "freeze." Acute perseverance occurs particularly when decision makers stand by a decision already made because they believe that changing it is a sign of weakness, even if all the information coming to hand suggests that a change of direction is necessary. Finally, there is mental and physical fatigue; after about 12 hours of intense concentration in complex crisis situations, the ability to make rational decisions begins to deteriorate, even in the fittest of decision makers.

Reducing the Impact of Stress

The ability of decision makers to cope with stress is dependent on a number of key factors that reduce the chances of their being affected by negative stress:

- The knowledge that they have of the area in which they are required to make decisions.
- Their experience in similar situations.
- The training they have undergone, including taking part in exercises, to prepare them for making decisions in stressful situations. In order to minimize the effects of stress on decision makers, pre-event training is essential but, although it is impossible to re-create reality in its entirety, that training must be as realistic as possible.
- The crisis response procedures that exist within their organization.
- Active support from their colleagues.
- Their ability to quickly adapt to varying demands.

- Their fitness, both physical and mental.
- Their temperament and suitability to be in the position of handling stressful events.

There are numerous examples of military commanders making decisions under stress but few from civilian crises. Some of the best examples of the latter are to be found in aviation. William Langewiesche's description of how, following an almost complete engine failure, Captain Chesley Sullenberger was able to land his plane, carrying 155 on board, on the Hudson River on January 15, 2009, is one of the most recent. In undertaking this operation, Sullenberger was, claims Langewiesche, "capable of exceptional mental focus," suggesting that "during the glide to the Hudson" he had been able to "ruthlessly shed distractions, including his own fear of death." It is worth pointing out, perhaps, that airline pilots are regularly given the opportunity to react to simulated emergencies.

Decision Stream

Decision streams utilize numerous components of business intelligence to aid business leaders and decision makers in analyzing data and ultimately making better operational decisions. The principles and practice of using decision streams adds a dynamic component to processes in crisis management that have been historically static. For crisis managers, decision streams' greatest benefit is the integration of decision support, decision evaluation, and impact analysis to determine the full and total implications of every crisis and associated actions. The use of streams is unique because users are able to quantify data previously in a qualitative format and attach a fiscal component to actions previously perceived to be nonfiscal in nature.

Decision Evaluation

Crisis managers using business or operational intelligence tools to evaluate decisions and action interactions are presented with graphical and textual outputs through tools such as Sync Matrix and similar systems. Sync Matrix was originally pioneered by Argonne National Laboratory, in support of the Federal Emergency Management Agency (FEMA) and the Department of Defense (DoD), to evaluate several complex emergency response programs, most notably the Chemical Stockpile Emergency Preparedness Program. Tools, such as Sync Matrix, allow crisis managers to view the complex interactions between decisions, actions, and reactions from the operational environment in a variety of graphical and data forms. These outputs then drive a data-based after-action or performance review process that has historically been qualitative in nature. The data-based reviews also assist crisis managers with the process of separating perceived gaps in performance from actual gaps in performance. Furthermore, when decisions are charted in real time and compared with predetermined benchmarks, crisis managers have the ability to trend responses and actions over a period of years. Multiyear trending allows managers to separate effective and ineffective initiatives over a prolonged period of performance.

Integrated Data Flow

Data generated during a crisis and reviewed following a crisis response can also be channeled

Case Study: Decision Stream at the University of North Carolina Health Care System

In 2006, the University of North Carolina health care system started aggregating and trending threat data through a database with the intention of utilizing decision streams as a decision support and planning tool. In 2011, following the collection of five years of data, response benchmarks and profiles were compiled for six categories of frequently occurring emergencies. These profiles measured and benchmarked the following components: (1) productivity loss during emergency response; (2) time lapse between warning receipts and message dissemination; (3) time spent conducting pre-planning, response, and recovery operations; and (4) loss of revenue/increase in expenses during the crisis.

Starting in 2012, all emergency responses and actions that fall into an established hazard profile are evaluated against the benchmarks listed for each of the four components listed above. Each component features an established range, with the expectation that a particular action or metric will fall within the acceptable range. Any and all outlying actions and/or metrics are subjected to after-action review and, if necessary, a root cause analysis.

Emergency response and actions falling outside the established categories are archived. Once five related responses are achieved and validated, a new profile is established. As of 2012, this new integrated system has resulted in around a $55,000 reduction in lost productivity by benchmarking emergency response teams for response time and alert activation accuracy. In 2014, the Office of Emergency Management and Business Continuity Planning intends to add four additional benchmarked components to all active and future profiles.

back into an integrated hazard vulnerability analysis (HVA) and associated business impact analysis components to challenge current ratings or profiles for specific hazards or threats. Although a single outlying data set is not sufficient to change all planning assumptions, it does, however, provide a point of reference for a response outside the assumed norm. These points of reference, over time, can be used to establish outer edges, or sigmas, of a response or action curve. In the case of crisis management and emergency response, these points represent the best- and worst-case scenarios. Periodic evaluations and statistical analysis are required of data sets to ensure the data inside these sigmas remain statistically significant and valid. As the results of an integrated HVA start to ebb and flow, so does the decision stream for certain hazards or risks. As a particular hazard increases or decreases in threat or impact, crisis managers can adjust the benchmarks accordingly.

Market Share and Fiscal Reductions

Businesses across multiple sectors have long used decision streams and other business intelligence tools, coupled with lean/six sigma principles, to streamline processes and reduce expenses. Although crisis management is not a “revenue-generating” discipline, crisis managers can contribute directly to cost savings and expense management. Integrated decision evaluations and HVAs can dramatically increase efficacy of continuity of operations as well as business continuity plans. If normal operations can be sustained longer and/or resumed more quickly, this will directly correlate with expense reductions and revenue stabilization.

Every action taken during a crisis has the opportunity to have fiscal impact, even those involving preservation of life safety. By using decision streams and business impact data derived from HVAs, crisis managers can know in advance what the potential impacts of a hazard are before it occurs. This allows the crisis manager to propose a solution or countermeasure. The rationale follows the same thread of a business unit requesting funding for a project that could increase revenue. In this case, the crisis manager is requesting funding for resources to preserve the revenue and/or market share already in place. The latter is especially true in service-oriented sectors, including health care, leisure and hospitality, and telecommunications. If customers are not being served by their primary provider choice for a prolonged period of time, they will find a new service provider.

Decision Support Tools

A decision support tool (DST) is a tool that assists in decision making rather than making a decision for the user. The tool can provide guidance and analytical or procedural information to help users make optimal decisions. The tool can be a written document providing guidance or a computer technology–based tool comprising written documents, a number of functionalities, and wizards to aid in the decision-making process. A computer-based tool, also known as a decision support system (DSS), is a system designed in the framework of intelligence (helps resolve a problem), design (allows development of alternative solutions to a problem), and choice (helps analyze the impacts of alternatives to determine the best decision).

The development of computer-based DSTs started in the 1970s in the DOS and UNIX platforms, which moved to the Windows platform in the 1990s. The majority of the initial versions of these tools were stand-alone software designed for a single user at any given time. The growth and research advancements made in networking (World Wide Web, the Internet, and telecommunication technologies), computing (processing speed, hardware memory, and graphic visualization), information sharing (availability of digital data), and programming have allowed development of DSTs that are knowledge based, implement artificial intelligence, and allow access to multiple users at once.

Advantages and Limitations

Though advancements in information technology in the 21st century have increased the popularity and development of computer technology–based tools, these tools still are riddled with limitations. The merits of these tools include the following:

- *Efficiency:* The tools allow better understanding of a problem and impacts of potential solutions, thereby resulting in faster decision making and time saving.
- *Effective:* Because of availability of information regarding problems, DSTs enable improved decision making and better decisions.
- *Participatory:* Because data and other ancillary information are readily available, the tools enhance communication and collaboration among participants.
- *Cost savings:* Because a group of users can use the same tool, DSTs reduce costs for labor and for technology and infrastructure purchase.
- *Satisfaction:* The tools assist in determining adverse impacts of different solutions to a problem. It is, therefore, possible to choose a decision satisfactory to decision makers.
- *Accessibility:* Use of the Internet/World Wide Web has increased accessibility of a DST to any individual interested in the decision-making process. These tools eliminate the influence of demographic/income/ethnic/cultural diversity of decision makers on decisions.
- *Promote learning:* Use of these tools and constant updating of information help

decision makers learn new concepts and better understand the relationship between a problem and potential solutions.

- *Increase organizational control:* By storing all information shared by decision makers about a problem, these tools work as a warehouse of information. Thus, they allow managers responsible for problem solving to choose the best solutions based on participant information.

The limitations of these tools include:

- *Overemphasize decision making:* Although DSTs support decision making, the success of a decision is influenced by social/political/cultural characteristics of the problem-managing organization. Hence, managers should decide the appropriateness of using these tools with regard to a problem.
- *Relevant information:* Because the information is public, citizens tend to believe in the relevancy of information. It is, therefore, imperative to check and update relevancy and accuracy of data and information.
- *Unanticipated effects:* Information availability is crucial for successful use of these tools. The amount of information available can influence users' final decision, thereby leading to chaotic decisions and other such effects.
- *Obscuring responsibility:* Decision makers rely on available data/information to make appropriate decisions. Decision makers may blame the tool for their actions rather than assuming responsibility. Decision makers and managers should understand the role of the tool in decision making, and developers must also understand the problem and provide relevant information.
- *Objectivity:* The tool can be used to rationalize certain decisions that might not be acceptable to the broader community. Hence, managers responsible for final deployment of a decision should account for this problem.
- *Status reduction:* Managers may argue that the tool can diminish their status in the overall organizational structure, thereby resulting in lack of reliability in the tool. Developers and users of these tools need to resolve the status issue.
- *Information overload:* DSTs can manage and reduce information load on a user. Developers and managers of these tools need to monitor user perception and provide adequate information to make a suitable decision.

Components of a DST

A DST comprises four main components: (1) a user interface allowing user interaction with the tool, and graphic functions to visualize outcomes and reporting tools; (2) an interactive database management system to access different sources of data, information, and knowledge; (3) a model-based management system comprising models and analytical tools and functions to analyze and interpret data to help in making decisions; and (4) the network and architecture of the tool that assists its deployment on a network for user-group access. A DST can also be classified based on its input (problems that need to be analyzed, associated data/information), user expertise (required expertise and knowledge of users to solve problems and analyze information), output (the final information that will be used in formatting user decisions), and result (the final decision made based on user inputs).

Future Trends

Successful deployment of each component and their interactions with each other is vital for the success of a decision support tool as well as for an organization's operation and technical decisions. These tools also need to be technically and economically feasible for use; must contain legal, regulated, and detailed information appropriate for the problem; and have information adequate to help users successfully make a decision. Hence, a DST must aid a variety of stakeholders to make usable decisions based on available information. Following are some of the issues that influence acceptability and adaptability of these tools and require further research:

- *Privacy/confidentiality:* Because participants share their personal information, protecting privacy of participants and maintaining confidentiality of user information will allow citizens to feel secure in using these tools.

- *Integrity:* The tools should be accessible, reliable, timely, and transparent, and they should meet expectations of citizens so that future participation can be encouraged.
- *Accountability/nonrepudiation:* To ensure interaction and participation of users in the decision-making process, it is required that providers and recipients of information are accountable for using and providing information.
- *Trust:* Increasing user trust will increase acceptability and usage of these tools. This can be accomplished by verifying information quality, accuracy, and relevancy, and by taking measures to protect IT infrastructure from failure. Though digital data availability has enabled providing updated information at a faster pace, these data are not always available publicly or are expensive to obtain and maintain. Attempts should be made to provide cheaper accurate and updated information.
- *Knowledge representation:* Data and information can be represented by different visualization techniques. The kind of information each technique depicts can influence the decision-making process. Exclusion of user knowledge or the assumption that the user is knowledgeable about a problem can influence eventual decisions. Understanding user knowledge and need is essential to design tools.
- *Sustainability:* Updating these tools and information is imperative. However, cost of hardware, software, and data can influence the sustainability of a tool.
- *Interactivity:* Tools should be interactive, which means they should allow transaction of information.
- *Scale:* Although each user's decision is crucial, an individual's decision might be different from that of a group of participants. It is, hence, required to decide the scale at which a decision should be made for effective and satisfactory decision making.

Dedicated Site

To effectively manage a crisis, key people must all know where to meet to gather pertinent trustworthy information, exchange ideas, and authorize organized actions in response to a crisis. A dedicated site equipped specifically to manage crisis will help accomplish effective crisis management, saving time, money, reputation, and even lives.

Organized Response

Without an organized response, a crisis will evolve through the disorganized activities of the people involved, which may have adverse impact on the people and organizations assumed to have responsibility and accountability for the results of the crisis. Effective crisis management can control and direct the evolution of a crisis. To do so, the organization with responsibility needs to bring key people together to understand the crisis and direct actions in response.

The velocity at which a crisis unravels and information and misinformation travels requires an equally speedy crisis management process that can be achieved only by having key people in close proximity for communication and discussion before authorizing actions that control and direct the evolution of a chaotic incident into an event with an organized response.

Characteristics of a Dedicated Site

A dedicated crisis management site must have the following characteristics: (1) It must be accessible under all weather conditions and circumstances because key people must be able to travel to the site; (2) the location must be communicated regularly to all key people; (3) it must be secure from unauthorized access both physically and technically (such as a cyber attack); (4) it must be equipped with many forms of communication; (5) it must be insulated from the most common threats so it is not involved in the crisis; and (6) to assist with maintaining its usefulness, the site must be exercised regularly using crisis management drills that also offer the advantage of training key people to use the crisis management process effectively at the site. It is also advisable to have at least one alternate site in case the primary site is disabled by the crisis.

Important capabilities of a dedicated crisis management site are multiple inbound ways to gather information about the crisis and multiple ways for outbound communication to help authorize response actions that control and direct the evolution of the crisis. Following are important inbound and outbound capabilities.

Runners are people whose purpose it is to run information and physical objects to and from the site—information as in commands to take actions, maps, pictures, and verbal information relays; and objects such as additional radios or cell phones or paper purchase orders for extra supplies. Most often, the site will be well removed from the crisis, so running can be internally within the site; however, if technology is unavailable, the runner may be the only real alternative.

Television and radio bring outside news of the crisis and can help determine the direction of the public's perception regarding the crisis. They can also help the team prepare public information statements to the press and public to explain the team's strategy and belay any fears about how the crisis is being handled.

Internet access can provide ways to monitor information from popular social networking Web sites and to receive e-mails from many sources containing information and even pictures and videos. The Internet can also be used for outbound communication to the public as well as to vendors and outside team members who are hands-on in direct response to the crisis. With the speed of Internet communications and the ability to lose control of the delivery of confidential communications, the Internet should not be used for confidential communications. Internet access should also be secure from cyber attacks through the use of firewalls that prevent unauthorized access. Inbound e-mails should be scanned for threats that could incapacitate the site's ability to communicate using the Internet.

Multiple methods for inbound and outbound phone calls help facilitate verbal communication between an organization's staff, concerned public, the press, and local government. Phones tend to be the most used form of communication, but at times they can be affected by the crisis and should not be the only form of communication available. It's helpful to separate inbound calls from outbound calls to prevent one single phone or set of phones from being made useless by excessive traffic. Phone communications should include both wired phones and cell phones, and can even include satellite phones. Every type of phone has limitations and the potential to be affected by the crisis, so the more means of communication a crisis management site has, the better chance it will have to fulfill its purpose.

Monitoring amateur radio can bring more information because it is used by government first responders to address public safety. In fact, most crisis management sites are also called emergency operations centers (EOCs); even though their purpose is slightly different, their form and functionality can be almost identical. If the site will also communicate with local government, it should have amateur radio capabilities.

Fax machines are also useful for communication, mainly outbound. Many news services and vendors will accept faxes to report on crisis activities and purchase supplies needed during the crisis. There are also fax services on the Internet and fax servers with the ability to both handle large volumes of fax communication and store the faxes for future reference.

Some computer applications can also help organize and document crisis handling to be used for verification of completed actions and also as future legal proof of whether certain activities were ordered at the proper time. These applications can be used from the Internet or can be located on servers in the crisis management site. Great care should be taken when obtaining an application, as it may be affected by the crisis.

Every dedicated crisis management site must have the capability of serving the people using it for the longest period of time it may be required. If people will be using the site for weeks or months, their creature comforts must be addressed in design and construction of the dedicated site's capabilities. Sleep areas, food/drink, kitchens, bathing facilities, health care, and other needs should all be considered before a dedicated site is deemed worthwhile.

The final and perhaps most important characteristic is that a dedicated site for crisis management should be as immune as possible to the things that would cause a crisis. Uninterruptable power supplies (large batteries) and generators as well as a fortified structure can help a dedicated site survive the crisis and be available for the crisis management team.

Conclusion

A properly equipped and utilized dedicated crisis management site can be a very effective tool allowing an organization to control the evolution of a crisis to limit risk and save time, money, reputation, and even lives.

Deforestation

Forests are generally defined by the amount of tree canopy cover; deforestation is removal of tree cover. Deforestation is the practice of removing tree cover and converting covered forested lands to nonforest uses, resulting in the permanent destruction of the forest. Deforestation accounted for an annual loss of 16 million hectares (39 million acres) of forest through the 1990s and dropped to 13 million hectares (32 million acres) annually in the first decade of the 21st century.

The Southern Hemisphere accounts for the majority of forest loss, with South America (4 million hectares [8.9 million acres]) and Africa (3.4 million hectares [8.4 million acres]) accounting for a little over half of global forest canopy loss. Forest utilization in the less-developed countries is a result of rapid urbanization, population growth, and economic demands for forest products. European forests have continued to expand, while those in North and Central America have remained stable. Australia has been losing forest since 2000 as a result of considerable drought-related issues and forest fires. The tropical areas are being deforested at a faster rate than other areas globally. For example, from 2000 to 2005, deforestation in tropical areas increased by 8.5 percent compared to the 1990s. During the same time, the loss of old-growth forest in Nigeria and Vietnam doubled, and it tripled in Peru. The largest forest in the world is the Amazon rainforest, covering 550 million hectares (1.3 billion acres). Sixty percent of the Amazon rainforest is located in Brazil, and the remaining 40 percent is located in the countries of Bolivia, Colombia, Ecuador, French Guiana, Guyana, Peru, Suriname, and Venezuela. Over the past 40 years, Brazil has deforested 60 million hectares (148 million acres) of the Amazon, primarily for cattle ranching (more than 60 percent) and subsistence farming (30 percent). As a comparison, the United States has deforested 215,228 hectares (531,840 acres).

Globally, the reasons for deforestation include agriculture production (i.e., fruit tree [banana], soybean, and palm oil plantations), clear-cutting (e.g., for pulpwood and charcoal), mining (e.g., open pit and large scale), the creation of livestock pastureland, human settlements, and infrastructural projects (dams, road systems). The most common reasons for converting deforestated land globally are subsistence farming (46 percent), commercial agriculture (32 percent), logging (14 percent), and for fuel products (5 percent), according to the United Nations Framework Convention on Climate Change (UNFCCC).

Effects

Deforestation results in soil degradation, water cycle disruption, loss of biodiversity, increased flooding and drought, and increases in carbon dioxide (CO_2) in the atmosphere. The removal of forest cover and vegetation exposes the soil to direct sunlight, resulting in drought conditions, and the nutrient-rich topsoil is lost to wind and runoff erosion, increasing sedimentation in streams, rivers, and wetlands, thus preventing future forest regeneration because of soil degradation. Ultimately, the severity of the topsoil

A peat forest in Indragiri Hulu, Riau Province, Indonesia, is deforested to make way for an oil palm plantation, a highly lucrative venture and one in which Indonesia is now the leading supplier. According to the WorldWatch Institute, deforestation of peat bogs and native tropical forests to plant oil palm plantations creates numerous crises, such as species endangerment, the uprooting of local communities, and the release of methane gases that contribute to global warming.

degradation results in its being unworkable, and the land becomes a barren wasteland.

The water cycle is significantly disrupted by deforestation. The process of transpiration is disrupted by the loss of trees and vegetation. Transpiration is the process of trees and plants drawing up groundwater, commonly with their roots, then releasing the water (evaporation) into the atmosphere via pores in their leaves. Over half of the water in the Amazon rainforest is circulating inside the trees and plants. Trees also absorb precipitation and runoff, thus preventing topsoil erosion. The loss of trees increases soil erosion and diminishes the replenishing of the water table. Trees also absorb heavy precipitation, and without trees, the unabated runoff can result in floods. Ultimately, the loss of water cycle results in the land becoming a barren wasteland as well as the surrounding area becoming susceptible to flooding.

The loss of trees, vegetation, topsoil, and the water cycle results in significant biodiversity loss. This is particularly acute in tropical regions, which harbor almost half of the Earth's species but account for less than 10 percent of the dry land. The tropical animal and plant species are very diverse and highly specialized to specific microhabitats and ecosystems. Deforestation in these highly specialized microhabitats can result in specific animal and plant species becoming threatened and even extinct.

Forests are like the lungs of the Earth, because they absorb and store carbon dioxide from the atmosphere (a biological process called biosequestration), which is converted to nutrients for the tree. When the tree dies and rots, is cut down, or is burned, the stored carbon is released as CO_2 back into the environment. Trees lost to deforestation result in more CO_2 being released in a small time window than trees dying naturally. Deforestation is estimated to be contributing to between 20 and 30 percent of the total of human-caused (anthropogenic) CO_2 emissions. These carbon emissions are a major contributor to climate change.

Conflict in the Forest

There are some positive and negative socioeconomic results from deforestation. On the positive side, deforestation can be viewed as making positive changes to the rural and remote forest people. The benefits are building communities, colonizing regions, and providing an economic base for impoverished areas. Harvesting of the forest allows for economic growth as well as the lumber for building homes, buildings, and factories. Roads and bridges are pushed through, which open areas for trade and provide transport routes, allowing new products in rural and remote areas. Small-scale farms can supply agricultural products to other regions and provide locals with a modest income.

These same perceived benefits have also created friction. First, economic and development decisions do not significantly include the indigenous people most affected by the plans. Next, not all areas are interested in the changes, and some groups view the changes as destroying their way of life. As a result, deforestation creates conflict (sometimes violent) between the local indigenous people and those modernizing under governmental approval. The conflict is also over ancestral rights and governmental rights, as the encroachment onto indigenous lands is seen as ignoring the rights and removing the livelihood of the indigenous people. Millions of indigenous people already make their living from the tropical forest through subsistence (hunting and gathering) and/or harvesting forest products. The challenge to governments is balancing forest use/conservation, economic development, and needs of indigenous people.

Reforestation

One solution to buffering the effects of deforestation is reforestation. Reforestation is beneficial to humans and ecosystems because it enables the capture and storing of carbon dioxide. Planting trees is critical in reducing the effects of deforestation because trees prevent flooding and erosion, reduce topsoil loss, and prevent increased sedimentation in streams, rivers, and wetlands. Reforestation benefits water bodies as well through aquifer recharge, storage, and recovery, and recycling inland rainfall. Tree planting and maintaining topsoil are essential for rebuilding natural habitats for plants and wildlife.

Denial-of-Service Attack

A denial-of-service (DoS) attack is a cyber attack intended to deprive users of a resource or service that they normally expect to have. Specifically, it is an attempt to render a computer or network inaccessible to its intended users by suspending the communications of networked computers to the Internet. The term is sometimes used interchangeably with distributed denial-of-service attack (DDoS attack) because this is the most common form of DoS attack, though they can take other forms. DDoS attacks come from multiple computers and systems, meaning that they are much more complex than simple DoS attacks and also much harder to protect against. DoS attacks constitute a significant threat to the operational functioning of any organization dependent on the Internet for a significant part of its operations. They can create significant functional crises that not only threaten the organization itself but also can have implications for public safety, as Internet-based systems can now be considered to be part of the critical infrastructure of society. They therefore require explicit consideration within crisis management plans. They may be conducted by terrorists, by criminals, or just for maliciously mischievous purposes.

Generally, DoS attacks do one of three things: they force the target to reset continually, they block communications between the target and its intended users, or they consume its resources to the extent where it can no longer appropriately respond to legitimate traffic. Bombarding the target with external communication requests is a particularly common form of attack. The target becomes saturated with these requests to the point where it is incapable of responding to any other form of traffic or it becomes so slow in responding that it is ineffectual for legitimate business. When DoS attacks are targeted at a network, every computer within the network is affected by the attack and experiences detrimental effects in functioning.

Ethics and Legality

DoS attacks have been specifically considered by organizations that provide and police Internet services and have been deemed to be unethical practices. The Internet Society's policy statement issued through its Internet Architecture Board explicitly states that disrupting the intended use of the Internet and wasting resources through such actions is both unethical and unacceptable. In addition, Internet service providers issue acceptable use policies that govern and restrict the ways their services can be used. DoS attacks violate virtually all such policies. In addition to being considered ethical violations, DoS attacks are often illegal according to the laws of individual nation-states. For example, in the United States, these are a serious federal crime carrying lengthy imprisonment penalties, and in the United Kingdom, DoS attacks these have been illegal since 2006, carrying a maximum penalty of 10 years imprisonment. Other countries have similar legislation and punishments.

Prevention and Motivations

Intrusion detection systems are likely to be of little use, as DoS attacks rarely hide themselves and are intended to be visible and obvious disruptions. DoS attacks exploit normal traffic routes, meaning that it is not an option to close routes in order to prevent attack. Prevention of DoS attacks generally relies on a combination of tools to detect attack, to classify traffic, and to respond appropriately. Ultimately, the aim is to block illegitimate traffic but still allow legitimate traffic. This is not straightforward, however, as the illegitimate traffic often closely resembles the legitimate, deliberately spoofing this. This means that many protection systems, such as firewalls, cannot differentiate between them. Attacks that exploit systems' vulnerabilities may be avoidable to a certain extent, but attacks that flood systems with communications are much harder to resist. There is a range of tools available for purchase that assist in defending against DoS attacks, and some of these have successfully prevented attacks in the past. Where operations depend on continuous Internet availability, there is a definite danger of DoS attacks, but vigilance and forward planning can still prevent attacks from becoming serious crises.

The motivations for DoS attacks are various. There may be ideological or political motivations, or vigilantism, or attacks may be used by states or governments as a form of censorship. There may also be less ideological motivations, such as extortion, where a business is asked to pay a "fee" to prevent DoS attacks by the extorter. It has also been suggested that DoS attacks could be used as a form of stock manipulation or to put competitors out of business; however, there is less obvious evidence that this is occurring.

Examples

Perhaps the clearest example of the problems that DoS attacks can create is the attack in 2010 that took the entire country of Myanmar (Burma) offline. The attack happened as Myanmar was holding its first election in 20 years. The ruling military claimed that the election heralded the transition to a democratic state, but there were doubts, both within Myanmar and internationally, as to whether this would be a sham. International observers and foreign journalists were not allowed into Myanmar to cover the election, which made the Internet vitally important as a communication tool to monitor events. This was not the first time that Myanmar had gone off-line; in 2007 the government allegedly severed the country's Internet links as a response to growing political unrest.

In 2011, following the posting online of a "recruitment" video, rumors began circulating that Anonymous (a decentralized anonymous online community that takes coordinated action toward self-agreed goals) was to attack the social networking site Facebook. These rumors resurfaced in 2012, shortly before Facebook's initial public offering in the stock market. Anonymous denied the rumors, and no such attacks appear to have occurred. However, Anonymous has claimed responsibility for a number of high-profile DoS attacks. These include a number against the International Federation of the Phonographic Industry, as a pro-piracy stance, as well as an attack against a child pornography site called Lolita City, intended to take the Web site off-line, an example of a DoS attack being used for vigilantism.

Department of Homeland Security (DHS)

The Department of Homeland Security (DHS) is a department of the United States' federal government, developed from the National Strategy for Homeland Security that emerged in the aftermath of the terrorist attacks on September 11, 2001. The organization saw several evaluations and modifications in 2005, 2006, 2007, 2009, and 2010. The department was created by integrating all or parts of 22 existing federal agencies and departments. DHS has five key roles in addition to efforts to strengthen the department itself: (1) preventing terrorism and enhancing security, (2) securing and managing U.S. borders, (3) enforcing and administering immigration laws, (4) safeguarding and security of cyberspace, and (5) ensuring resilience to disasters. Each of these roles centers on domestic safety and security and includes and influences crisis management efforts.

Organization

DHS is run by the Secretary of Homeland Security, a position in the president's cabinet and part of the presidential line of succession after the Secretary of Veterans' Affairs. After the inclusion of many preexisting agencies and the development of the new department, DHS has grown to be the third-largest American cabinet department after the Departments of Defense and Veterans' Affairs, with over 200,000 individuals. The department is part of the United States Homeland Security Council (HSC), along with the departments of Treasury, Defense, Health and Human Services, and Transportation, as well as the Federal Emergency Management Agency (FEMA) and the Federal Bureau of Investigation (FBI).

Many of the agencies and departments that became part of the Department of Homeland Security had previously played a role in crisis, emergency, and disaster management. The groups that merged into DHS included, among others, the Office for Domestic Preparedness, FEMA, the Strategic National Stockpile, the National Disaster Medical System, the Nuclear Incident Response Team, Domestic Emergency Response Teams, the National Communications System, and the Transportation Security Administration. As various agencies and departments became part of the new department, many were reorganized into newly created groups or became part of other, often larger, organizations within DHS. For example, the responsibilities of the Office for Domestic Preparedness, previously part of the Justice Department, now became part of FEMA, which was, in turn, now part of DHS.

Crisis Management and Other Operations

DHS is involved in many levels of crisis management. According to the Department of Homeland Security Act of 2002, DHS is responsible for giving crisis management support to local, state, and private entities that take part in information, analysis, or warning systems. This support often emerges after threats to or attacks on those systems.

Through DHS-related laws and presidential directives, as well as the National Strategy for Homeland Security, several new policies have emerged related to the operation of DHS and other federal agencies and crisis preparedness and management. Homeland Security Presidential Directive-5 required federal departments and agencies to adopt the National Incident Management System (NIMS). Following from NIMS, the National Response Plan (NRP) was created in 2004 and replaced in 2008 with the National Response Framework (NRF). The NRF Resource Center falls under the purview of the Secretary of Homeland Security, the head of DHS. As an incident-management system, NIMS includes efforts to prevent, prepare for, respond to, and recover from a wide range of crises, emergencies, and disasters. These management efforts include not only helping other organizations in their efforts but also ensuring that various groups can work together effectively.

Problems

When DHS was formed, complaints quickly emerged about the potential problems of combining a vast range of operations and agencies within one parent department. For some critics, the primary problem was the diverse nature of duties that the agency would now support. For others, the department's creation was seen as a political maneuver to allow the government to point to changes being made and less of an actual fix for problems of communication, prevention, and response that seem to have emerged with the September 11 terrorist attacks. Critics who ascribed to both of these ideas reemerged in the wake of Hurricane Katrina and its effects on New Orleans, Louisiana, and the rest of the U.S. Gulf Coast. Some argued that the problems with federal and other government responses to Katrina demonstrated the flaws of having a large agency responsible for too many things, demonstrating that DHS was being stretched too thin. Others claimed that the problems with the Katrina response revealed that the creation of DHS had not solved preexisting government agencies' troubles with crisis, emergency, and disaster prevention, preparedness, response, and recovery.

DHS has also been charged with several accusations of waste, mismanagement, and ineffectiveness. After Katrina, a Government Accountability Office (GAO) report found widespread waste and fraud totaling over $2 billion. The report and its findings were widely covered in American media, presenting the general results and specific examples of financial mismanagement to the public. Investigations by the media also revealed other problems, including the incorrect use of the data mining tool ADVISE (Analysis, Dissemination, Visualization, Insight and Semantic Enhancement).

Conclusion

DHS emerged as a transformation of crisis management efforts in the aftermath of September 11, 2001. The department was formed to include a wide variety of smaller government offices and agencies in an effort to create a more comprehensive crisis, and incident-management system. However, concerns have emerged as other disasters, crises, and emergencies have revealed problems, leading to attempts to change DHS's organization and duties to make it more effective.

Disaster, Definition of

Disasters are caused by hazards (natural, human-made, or some combination of both) when they intersect with a vulnerable population, causing severe damage or destruction to people, resources, and the surrounding environment. To prepare for and respond to disasters, crisis management must identify potential threats to a group, which includes both considering the hazard that will prompt the disaster and the population it will affect—a wide range of factors. In addition to physical effects such as human deaths and injuries, and damage or destruction of human-made and natural landscapes, disasters may directly or indirectly impact social and political structures, causing economic problems and environmental destruction and loss of life.

Despite these general characteristics, many people and organizations offer various specific definitions of disasters. People often casually use the term *disaster* interchangeably with related terms like *catastrophe*, *crisis*, or *emergency*. Defining disasters is complicated by the wide range of events that can fall under the term that can be framed by their causes (such as natural hazards) and their effects (widespread devastation, large numbers of a population killed or left homeless).

The disaster itself is often considered to cover a set period of time marked by when a natural hazard's direct effects began and ended or between a human-made hazard's release and cleanup. However, the effects of a disaster and the recovery period after it can last beyond that time, concluding long after the disaster itself is considered to have ended. Moreover, social circumstances and

Homes in Henryville, Indiana, lay shattered five days after a series of tornadoes struck southern Indiana on March 2, 2012. Thirteen people died and hundreds were left homeless. President Barack Obama issued a major disaster declaration on March 9, two days after joint preliminary damage assessments were completed in six counties. By definition, a natural disaster is considered to cover a set period of time marked by when the hazard's direct effects begin and end, but the effects of a disaster and the recovery can last far beyond that.

human changes to the environment that can affect a disaster predate the direct effects of the hazard on a population. A disaster is not solely the product of the hazard involved but also emerges from the affected population.

Natural and Human-Made Disasters

Disasters are generally divided into two broad types: natural and human-made. Natural disasters involve a hazard produced by the environment, such as a hurricane, earthquake, or blizzard, for example, Hurricane Katrina in 2005. Comparatively faster-moving natural hazards like tornadoes or floods are generally classified as disasters, but slower-moving and longer-lasting hazards like droughts are not always referred to as disasters; however, some researchers challenge this and argue that, although slower to develop and progress, events like droughts should be considered natural disasters.

Human-made disasters emerge from agents produced by human beings, such as nuclear waste, oil products, or manufactured chemicals, such as the Bhopal gas leak in 1984. Although many human-made events are considered disasters, some are often excluded. Wars, for example, are rarely classified as disasters but instead are considered by their own terms. Still other events, such as terrorist attacks like that of September 11, are only sometimes classified as disasters, otherwise contextualized within a distinct category apart from disasters and events like wars. In some cases, one type of disaster can cause the other, further complicating the definition of a disaster, as was the case with the Tohoku earthquake and tsunami in 2011, which included the Fukushima

Daiichi nuclear disaster, when a natural disaster led to a human-made event.

Disasters may also be differentiated as sudden or rapid-onset or as slow-onset disasters, either type of which can be either natural or human-made. Sudden or rapid-onset disasters include relatively unpredictable and unexpected hazards like chemical spills or tornadoes. These rapid-onset disasters leave relatively little time to prepare or respond, often striking people while they are still unaware of the disaster's existence or progress. Slow-onset disasters include events that can be tracked over longer periods, such as hurricanes or famine. These disasters often give people more advance notice and time to prepare, but that time helps only if they have the resources to make appropriate preparations.

Increasingly since the 1970s, many experts and organizations, such as the Red Cross, view disasters as the intersection of a hazard and a vulnerable population. In this perception of disasters, "hazards" refer to events or processes that pose a potential risk to human populations. These hazards include naturally occurring events such as hurricanes or earthquakes and human-made events such as chemical spills. Vulnerable populations are those who are less able to prepare for and recover from a disaster, based on certain characteristics such as age, gender, or economic or social status. This vulnerability goes beyond simply being affected by a hazard and into a consideration of social and economic status, including factors like poverty, gender, race, age, and disability. Crisis management therefore must not only consider the physical effects of a disaster but also deal with a variety of populations that have different needs following a disaster.

Some argue that the distinction between natural and human-made disasters is not as important to how disasters are managed by officials or experienced by individuals or groups as is the speed with which they begin and happen or the scale of the disaster. This includes the idea that larger disasters (by scales such as the affected land area or population), whether natural or human-made, must be managed in a different way than smaller disasters because they result in the need for more resources to be used, more organizations involved in response and recovery, and often more long-term consideration to successfully manage the disasters and their effects. Within this framework, so-called natural disasters may be considered to have effects that are human-made (particularly when considering vulnerable populations).

Disaster Assessment

Disaster assessment is an essential part and ongoing activity of any disaster or crisis. There is a misconception that disaster assessment is a one-time activity during disasters. Actually, disaster assessment is important during all phases of disasters to make an accurate assessment of the situation, needs, resources, and progress during and after the event.

What Is Disaster Assessment?

The concept of disaster assessment depends on understanding what a disaster is. A disaster is an extraordinary event whose consequences lie beyond the capabilities of the local community to respond. When consequences of a disaster exceed the ability of the community to contain them, there is a disaster. The community needs external help to control the situation.

Assessment is a critical activity and an essential component of disaster preparedness and management. In disasters, assessment usually includes but is not limited to situation assessment, needs assessment, available resources, and recommendations. Situation assessment describes the disaster and its impact on the community, the infrastructure, and the environment. Needs assessment determines needs of the affected community classified according to their urgency to the affected community. For example, in a disaster with many injured but with the infrastructure intact, urgent needs would be medical aid, but in another situation, shelter, food, and water may be more important.

The process of disaster assessment has five objectives:

- To determine the impact of the disaster on the community
- To determine the needs and their priorities to the affected community
- To determine the resources available
- To determine development or mitigation opportunities
- To monitor the recovery process

Who Will Perform the Assessment?

The assessment of any disaster is an important step for all the following actions needed in a disaster. External aid or funds usually depend largely on valid assessments indicating a real need for aid, the extent of this aid, and its urgency. Meanwhile, most disaster situations are characterized by urgency and disruption of regular organizational processes. Therefore, choosing the right team to do the assessment is a vital step toward response to any disaster.

There may be different teams assessing the same disaster. Every organization concerned with the disaster may have its own assessment team. For example, if a certain country is experiencing a disaster following a devastating earthquake, the country will have its own assessment teams assessing the situation and sending reports to all stakeholders. Humanitarian organizations, either international or national, will usually have their own assessment teams and will not depend solely on the data developed locally. The assessment team composition should reflect the type and the environment of the disaster. The team composition usually follows policies and guidelines of the organization carrying out the assessment. Appointing a team leader with expertise in the type of disaster under assessment is vital in flexibly responding to changing circumstances. Sometimes, help from the local community may be needed.

Format of the Assessment

The format of the assessment differs slightly between different organizations, according to the main mission and objectives of each organization or authority. For example, United Nations organizations conduct comprehensive assessments covering nearly every aspect of the disaster, whereas a volunteer medical organization focuses mainly on health issues, opportunities for preventing disease, and medical needs of the affected populations. However, most of the assessment elements are similar among different organizations. Elements of assessment usually include some or all the following items:

- Situation assessment
- General description of the situation and population affected
- Infrastructure damage
- Environment
- Shelter
- Food
- Water
- Sanitation
- Health
- Others (e.g., political situation, security, transportation)
- Needs assessment
- Immediate
- Long term
- Resources assessment
- Forecasting

Situation Assessment

The situation assessment should be as comprehensive as possible because any item missed during initial assessment may affect the following

Case Study: Assessment of the Marmara Earthquake, Turkey, 1999

The Marmara earthquake (7.4 on the Richter scale) hit northwestern Turkey on August 17, 1999, early in the morning. It was a major disaster that resulted in over 17,000 dead and some 32,000 injured.

The local government authorities and a multitude of international organizations responded to the event. The government of Turkey invited the World Bank to help in the disaster assessment. The World Bank had already sent two teams to the disaster location to assess the event. This was important to the Turkish government because it would help in assessing the damage and the forecasted funding needed to reconstruct from the damage. The two teams of the World Bank did not start their missions simultaneously. The Emergency Recovery team began its work first, on August 24, 1999, and its mission was to assess damage. The second team started their work on September 1, and its mission was to make an economic assessment. The reports of the two teams were synthesized after the end of the assessment on September 10, 1999.

The initial assessment of the teams resulted in realizing the great damage caused by the earthquake. The assessment also formed a good base on which the World Bank and local government could anticipate the funds needed for reconstruction and the sectors that sustained the most damage.

Although the assessment by the World Bank teams focused mainly on evaluating the cost of the damage, it was mandatory to assess the entire disaster from its different aspects. The assessment report did not include only costs representing how many buildings were damaged or how much money would be needed for reconstruction. The assessment included elements that need to be evaluated in any disaster to give an appropriate understanding of the disaster. It included estimated damage costs for housing, infrastructure, environment, roads, bridges, railways, education, health, and other elements.

Uncertainty and difficulty in getting data arose as a problem during assessment and preparation of the reports, although the assessment teams coordinated with the local government and made site visits to get information from the affected population themselves and to conduct a visual assessment of the damage.

The assessment teams stressed in their report that the numbers in the report were their best estimates and based on the data available at the time of assessment. They also stated that these numbers needed updating when new data became available.

This is a good lesson to learn in assessment. Because disasters are not static events, assessment also should not be a static configuration of the underlying disasters. Any disaster comes into successive phases, during which numbers may change dramatically. Therefore, monitoring and continuous assessment during all phases of any disaster is the best way to get a reasonable conceptualization of the baseline data and changes as they occur.

Although the main focus of the World Bank report was to assess damage cost, it was mandatory as a disaster assessment to include some details about other effects of the disaster on the community. The assessment report did this, dividing the impacts into sectors:

- Housing
- Municipal infrastructure
- Health
- Education
- Environment
- Transportation
- Telecommunications
- Electric power
- Oil and gas

This breakdown of the assessment not only helped in covering data from various fields but also assisted the local government and the helping organizations in identifying the most affected areas. This would in turn result in efficient use of resources.

After the Marmara earthquake, the initial disaster assessment by the local government indicated great damage that exceeded the capacities of the official authorities to respond to. Therefore, the government of Turkey urgently requested international help. Help requested included emergency aid, firefighting troops, and recovery and reconstruction assessment. According to the Red Cross and Red Crescent societies, following the Marmara earthquake, about 50,000 people were rescued from beneath rubble, but 98 percent of these were rescued by local residents!

Studying different assessments and reports made during and after the Marmara earthquake indicates the importance of preplanning assessments to be ready and applied timely in case a disaster occurs. Good preplanning and effective performing of the assessment process provides a better chance for rapidly identifying urgent needs to save people and spotting long-term needs to save their future lives.

actions taken to relieve the disaster. The initial assessment forms the baseline of data for the following assessments during the successive phases of any disaster.

General description of the situation: This describes the type of disaster and its impact on the community. Demographics of the population are detailed to a suitable degree. Initial assessment involves appropriate information about the estimated number of the population affected, their lives, and location.

Infrastructure damage: Assessment evaluates the extent of damage to the infrastructure. The degree of damage to different utilities projects itself on both the affected population and the upcoming assistance. Damage to water resources means an urgent need to supply water to the affected population to avoid the many problems that result from lack of clean water. This priority needs mitigation as soon as possible.

Environment: Are there any environmental causes behind the disaster? What are the environmental conditions at the time of assessment? Also, it is necessary to describe any environmental risk factors that are affecting or may complicate the situation and the damage caused to the environment from the disaster.

Shelter: In certain circumstances, alternative shelters are a priority. Shelters need to be suitable to the local community.

Food and nutrition: A general description of the regular food types is provided, along with possible substitutes. Assessment includes the effect of the disaster on the current stock of foods and availability of any substitutes. Other changes affecting availability of food are also described. Prices changes and shortages of certain foods essential to certain vulnerable groups like children or pregnant women are described. Documentation of the nutritional status is important because it affects urgency and types of food supplement needs. Indicators of food shortages like nutritional diseases and nutritional status of special need groups are described. Assessment describes any problems in delivering food to the affected groups.

Water: Because water is vital for life and hygiene, comprehensive data are important, especially in situations where large numbers of the population are displaced. Assessment includes quantity and quality of water available to each person, effect of the event on the regular water resources, availability of substitute resources, and time and effort needed to get water.

Sanitation: The impact of the event on the sanitation system of the community is described. Also, the current condition of the sanitation system and the degree to which it copes with the current situation is documented. In case of any displaced populations, accounting for the sanitation structure and any needs is of paramount importance. Any problem in sanitation systems may be reflected rapidly on the public health of the affected population and result in complicating the situation. Assessment includes number and cleanliness of latrines available to the affected groups and whether there are any problems in using them. Can vulnerable groups like women and children use the latrines safely?

Health: Assessment includes a clear description of the health status of the affected population. Both direct and indirect impacts are needed. Most important are:

- Mortality and morbidity rates
- Morbidity and mortality rates in vulnerable groups
- Causes of morbidity and mortality
- Presence or absence of outbreaks
- Any other issues expected to affect the health of the affected population

In some disasters, injuries are a core concern, for example, in earthquakes. The number of injuries needing rapid intervention may overwhelm local resources. In these cases, the best solution is to get the nearest medical help. Depending on international external medical aid for rapid intervention may result in complicating the situation rather than solving it. External aid takes time to be available that may be not practical with a situation of tens or hundreds of injured in need of rapid intervention.

Also, it is usually better to depend on local medical personnel who are aware of the local community, and its culture, language, and common diseases than foreign medical aid staff. However, in some disasters, expertise in certain fields may be needed. Therefore, careful assessment of the health situation and demands is important in allocating the best possible aid to the affected populations either immediately or on a longer-term basis.

Other (security, political, transportation, etc.): Considering other critical items during the assessment process may be as important as any of the previous items. For example, a general description of the political situation is beneficial in most disaster situations, but in some situations detailed description is mandatory. In complex humanitarian crises, assessment should describe clearly if there are any political conflicts or dominations of certain parties in the situation. Also, it should be documented whether there are any political obstacles that may hinder external aid.

Like the political situation, security is a quite important point to consider. Security affects not only the population struck by a disaster but also the future of any external aid to the area. Stable political and security conditions in an area make assessment easier and assure volunteer organizations about safety of their teams in the area.

The Process of Disaster Assessment

Like any assessment, disaster assessment passes through successive stages. Usually, a disaster assessment involves the following stages: planning the assessment, collection of data, analysis and interpretation, recommendations and reporting, and finally continuous monitoring throughout the duration of the disaster.

Most disasters occur suddenly or shortly after a narrow period of warning, so preplanning for disasters is important. Included in preplanning for any disaster is the assessment planning.

Collection of data takes one or more of several forms of standard data collection, and this depends on the conditions of the disaster and the feasibility of applying one type rather than another. Common tools for collecting data are the following:

- Surveys or questionnaires
- Interviews
- Direct observation by team members
- Using databases of previously processed data

The process of data assessment is ongoing. It starts with planning, depending on the disaster situation. After planning comes collecting data and then analyzing the data to get meaningful information. Information produced is then used to formulate good decisions related to the disaster situation. Decision making, especially in disasters, should be fostered by implementing solutions and monitoring them to apply any amendment needed in a timely manner.

Disaster Declaration

The emergency management profession has a saying: "All disasters are local." Although this is accurate for those experiencing the effects of an incident, it does not account for the political process involved in having an incident be declared a "disaster." Only the president of the United States can invoke that status over a national incident. A complex formal process has to take place involving local, tribal, state, and regional emergency management in order to get that language assigned. When the president declares a disaster, another formal process begins to implement a prescribed campaign to assist in disaster response and recovery operations outlined in the Robert T. Stafford Disaster Relief and Emergency Assistance Act (Code of Federal Regulations, Title 42 The Public Health and Welfare, Chapter 68, Disaster Relief).

The process of disaster declaration begins at the incident. An incident is a risk that has escalated to a crisis and impacts human populations. These risks may be natural (e.g., earthquake, flood, hurricane, tornado, volcano eruption). These risks may be technological (e.g., cyber attack, terrorism, oil spill). Whatever the type of risk may be, it has intersected with human populations and affected their world.

When the incident begins, the operational response is at the local level through first responders: local fire, law enforcement, and emergency medical personnel. If a disaster response plan exists in the jurisdiction, it is activated at the time of the incident. Local governments often have a memorandum of understanding (MOU) in place with neighboring towns, cities, counties, or regional organizations to assist with these efforts. The MOU assumes that resources named in the memo will be used if available. If both partners in the memo are responding to a similar incident in each jurisdiction, response capabilities remain at their place of origin.

An emergency management department may coordinate local response efforts. These are staffed by professional personnel who work full-time on readiness, response, and recovery programs associated with emergencies and disasters. However, many local governments do not have a dedicated program for this function. Those duties may be assigned to a city manager, mayor, or volunteer coordinator; some local governments may not have an emergency management contact at all. In such cases, local law enforcement coordinates emergency management activities. Whoever is responsible for managing the incident is also the point of contact with state emergency management personnel and is responsible for situation reports, requests for assistance, or activating an MOU. Local facilities for record-keeping about response activities is where data are generated to support the need for a disaster declaration.

When an incident is managed through local response efforts, no formal disaster declaration is issued. If the incident is too extensive to handle locally, officials at the local level request assistance from the governor of the state. This is the next step in the disaster declaration process.

The governor of a state has a variety of operational resource capabilities available to aid local jurisdictions. He or she may activate the state emergency operations center (EOC) to coordinate available state assistance. Depending on the size and scope and impact of the incident, the EOC may be partially or fully activated. If enough local response organizations have requested assistance and it becomes necessary, the governor may proclaim a state of emergency. A series of specific steps must be followed for this process to be legal. These differ from state to state, but most require situational assessment that shows how many jurisdictions were impacted, the potential for other areas to be impacted, and an assessment of life-supporting and critical infrastructure resources that are needed.

When a governor proclaims a state of emergency, the state emergency operations plan (EOP) is activated and provides for the use of state resources. Some of those actions or resources include use of the National Guard, invoking existing mutual aid agreements, and a request for assistance from voluntary or community-based relief organizations (such as the Salvation Army or American Red Cross). The role of state emergency management staff is to assist local and county officials with response operations. The state EOC establishes liaison with county and local officials.

The documentation that began at the local level continues throughout the response operations; critical to this process is the collection of financial data. The state will need to provide evidence for the cost of response operations (e.g., first responders' overtime, use of resources, services provided under an MOU that must be reimbursed, etc.).

Also critical to the documentation process is a preliminary damage assessment (PDA). This takes place at the local level where the incident took place and expands as far out as the damage has occurred. States vary in the process of a PDA, but the goal is to determine the extent of damage to individuals, families, and public infrastructure systems. Determining the scope of damage can determine whether the situation warrants a federal disaster declaration.

When a PDA occurs depends on the severity of the incident and the accessibility of the site. For obviously catastrophic events like the bombing of the World Trade Center in New York City, the PDA was completed almost immediately post-incident and a disaster was declared quickly. For an avalanche in Alaska, PDA teams may not have access to the area for weeks. In such cases, a PDA team might use an airplane to fly over the area to assess the extent of damage, with an on-site visit when it is safe to have people enter the area. Once a PDA has taken place, the governor can request federal assistance.

The Governor's Request for Federal Assistance is a formal written document submitted with the assistance of a regional office of the Federal Emergency Management Agency (FEMA). There are 10 FEMA regional offices that work in partnership with specific states. State Liaisons from FEMA have pre-established relationships with each step and are available to support and partner with state emergency managers who construct the governor's request.

If the president does not declare a disaster, the cost of response and recovery operations lies with the state and local governments. If federal assistance is denied, amendments may be made to the request, and it can be submitted for reevaluation. Most denials happen because the incident does not exceed the threshold of the state and local government response capabilities. Although it may be catastrophic to the individual or community experiencing it, the incident may not be large enough to call upon federal resources; it can be handled with local and state capabilities.

When a state can document how an event will exceed its capabilities to respond to an incident through the formal Governor's Request for Federal Assistance, the president issues an emergency or disaster declaration.

When an incident occurs on the land of a federally recognized tribe or native Alaskan village, there is a variation in the declaration process. The tribe or native Alaskan village has the choice to apply for a disaster declaration directly to the federal government or as a subgrantee of the state in which it is located. Should it choose the direct route, the tribal government applies for federal assistance in the same manner described above regarding the governor's request. If a disaster declaration is granted, the tribe or native Alaskan village manages the disaster response itself and receives recovery program funds directly through FEMA. Should it choose to be a subgrantee, the state uses data, evidence, and information from incident damages to the tribe or native Alaskan village in its PDA to establish the state damage threshold. If a disaster declaration is granted, the tribe or native Alaskan village receives recovery program funds through the state, which manages the incident.

Once the president issues an emergency or disaster declaration, recovery programs are made available to the state, tribe, or native Alaskan village for eligible items according to the Robert T. Stafford Relief and Emergency Assistance Act.

Disaster Declaration Officer

A disaster is an unexpected event that goes beyond an affected area's capability to respond in terms of saving people's lives, protecting property, and sustaining social, environmental, financial, and political constancy of the affected area. Disasters are managed at the local and state levels by sharing the responsibility to protect people from disasters. In some cases, the capacity of local and state governments may be insufficient to respond to a disaster effectively. In the event that a disaster or chaotic situation occurs or is foreseen, and there is a lack of resources to deal with it, a disaster declaration process must be initiated by the authorized person.

The disaster declaration officer is the person who is appointed and authorized by law to officially declare a disaster. She or he is also the person who is knowledgeable about the magnitude and the consequences of a catastrophic event that requires taking an action to manage it at the local, state, or federal level by allocating resources. She or he activates the disaster response plan in order to convey necessary assistance to people waiting for help.

Local Disaster Declaration

Local response is the first stage for all disasters. When the consequences of an unexpected event such as flood, fire, storm, earthquake, epidemic, drought, or sudden and severe energy shortage, seem greater than the local resources to adequately respond, a local disaster declaration is issued to activate the jurisdiction's emergency operations plan. This declaration states the type of disaster, the date(s) of occurrence, and the name(s) of affected area(s) and must be issued by the city council or the board of supervisors or the person authorized by local law within 10 days of occurrence in order to qualify to receive state assistance; it must be renewed every 14 days. As soon as a local state of emergency is declared, all outside assistance requests are managed by the local office of emergency management. The local emergency management coordinator takes responsibility for dispatching all resources sent to the affected area(s).

State Disaster Declaration

When a disaster strikes, local powers immediately take action for necessary emergency response activities to evacuate the disaster's victims, ameliorate distress, and protect life and property. If local capacities are not sufficient, the local governing body requests the state to declare a state of emergency in order for the state's emergency plan to be activated. The local governing body makes the request to the state within 30 days of occurrence if it is determined that conditions are greater than the local jurisdiction can handle in terms of managing the services, human resources, equipment, and facilities needed and require additional resources from the state. The request explains why state assistance is needed and contains a copy of the local disaster declaration and initial damage estimates. Once the state disaster declaration is proclaimed, state resources are deployed to the affected area(s) promptly. Those resources may be extended according to the type of disaster and assistance required, including equipment, personnel, supplies, technical support, and crucial services such as debris removal, security, traffic control, vaccines, transportation, and traffic control. The state disaster declaration may also make assistance available to the residents in need. Some governmental entities may be eligible to receive a contingent fund loan in order to lessen the impact(s) of the disaster.

Major (Federal) Disaster Declaration

The regional emergency management office monitors disaster conditions and assistance activities before, during, and after the disaster by being in contact with state officials. After the local and state resources are utilized, if there is still a need for additional assistance to better respond to the impact(s) of the disaster, a major disaster declaration is requested from the president by the governor of the state within 30 days of occurrence to have federal assistance.

Before submitting the request, state and federal officials do a joint preliminary damage assessment (PDA) to estimate the scope of the disaster and its effects on people and public facilities. In general, the PDA is prepared prior to the submission of the governor's request. If a severe or calamitous event occurs, the governor's request may be submitted prior to the PDA. Later on, the estimation of the type and amount of federal assistance required is prepared. Additionally, eligibility for federal disaster assistance is reviewed with the regional emergency management director.

The governor's request is made via the regional emergency management office by submitting a summary of the significance of the event; the results of the PDA; the assistance given by federal, state, local, and private agencies; the reasons why the governor requests federal assistance; and a recommended course of action for the president. The regional emergency management office sends the request to headquarters with its recommendations. The details of the request are evaluated and then submitted to the president.

The president makes the decision whether to approve the declaration; approval activates a group of federal programs to support the response and recovery activities. The request is turned down if it does not comply with the recommended criteria of approval. The governor may appeal a disapproval. The appeal must be submitted within 30 days by presenting further new information for reconsideration of the original request. When the major disaster declaration is approved, some or all of the federal disaster assistance programs such as individual assistance, public assistance, and hazard mitigation assistance are activated.

Rescinding the Declaration

When the circumstances are stabilized and there is no longer a need to have special orders in effect, the declaration is rescinded. Upon rescinding the declaration, the local office of emergency management is notified.

Disaster Drills

Disaster drills, or exercises, are tests of the ability to respond to crisis situations designed to familiarize participants with the processes involved, ensure rapid and efficient action, and ensure that people are able to work well together. There are four main types of exercise. Tabletop simulations involve working one's way through a scenario. Command post exercises are designed to test command and control functions. Emergency procedures drills can be used to test procedures such as mass evacuation or rescue. Finally, field exercises are the most extensive and realistic option, but also the most exacting and expensive one. The remainder of this article concentrates on drills in the field, which usually mean extensive outdoor work.

Exercises can be used to test and evaluate plans and procedures and to show their weak points. They can help clarify and familiarize people with emergency roles and responsibilities and, in particular, help organizations and individuals to work together during unfamiliar situations. Hence, drills usually have an education and training function, and they can highlight the need to extend this in particular directions. They can also highlight inadequacies in equipment or staffing. Drills are useful for improving the quality of messages exchanged during a crisis and to make information exchange and usage more efficient. Lastly, exercises can help garner support for disaster risk reduction and can thus have an impact on relevant policy. Typically, a field exercise may take 6–24 months to plan and 8–48 hours to run. It is carried out in real time and involves the typical stresses of the job.

Designing a Drill

The first step in designing a drill is to assess the capabilities of organizations that will participate. These include the ability to design, run, and benefit from the exercise and the presence of sufficient funds, time, and personnel to realize the project. An assessment must therefore be made of personnel, skills, physical facilities, and communications equipment. It is also necessary to assess attitudes in order to ensure that an exercise will have sufficient support at all levels within the participating organizations. Assessment of costs will determine which resources can be dedicated to the exercise. Estimation of costs should include staff salaries and overtime, contract and consultant services, equipment and materials. and, where necessary, the hire of facilities.

Once the feasibility study is ready, a steering committee needs to be appointed under the guidance of the general director of the exercise. To conduct the exercise, there will need to be one or more controllers, as well as groups of simulators, players, and observers (Figure 1).

An exercise is usually based upon a real event from the past (the reference scenario), updated to conform to modern conditions (Figure 2). To be similar to a real crisis situation, it is necessary to launch the simulation without informing the participants in advance. In practice, this involves so many complications and liabilities that very few organizations are able to do so. Hence, most drills are fully anticipated by participants.

Figure 2 The use of a scenario or reference event in the construction of a master sequence of events

A disaster field exercise needs to be planned, executed, and evaluated. It must be created in response to clear objectives that can realistically be achieved in the available time and with accessible resources. Planning should involve estimating the needs (for example, with respect to training or benchmarking crisis responses). Once the scope and objectives have been established, it is usually necessary to write the master narrative based on the reference scenario. This details the sequence of events that will have to be responded to by the exercise players. It also defines the expected actions. In many cases, narratives are accompanied by a series of situation reports that detail the progress of the crisis after set time intervals. Time is usually compressed to some extent so that the simulation can fit into the time available to conduct it. A further subset of the main narrative is the set of emergency messages that will be distributed during the simulation and that will solicit responses from the players. The narrative is compiled in the form of a master sequence of events list (MSEL). Finally, the exercise designers allocate tasks to participants, including the simulators, players, and observers.

The Participants

The exercise controller (or controllers, if it is a large, complex simulation) should have complete authority over the drill and must ensure that it fulfills its objectives. Using the flow of emergency messages, the exercise controller can speed up or slow down play in order to maintain the momentum of responses. The controller must solve problems as they occur and finally stop the exercise once it has met the defined objectives—or if it goes seriously wrong.

The simulators are responsible for sending emergency messages. They usually work in isolation from the players. All groups should be given a full briefing on the aims, scope, and nature of the exercise (Figure 1), with subsidiary briefings to explain particular roles. All participants are required to monitor safety and empowered to call a halt to operations if it is compromised. There should also be one or more safety officers who are concerned with nothing else. An evaluation of risks to safety should be conducted before the exercise is launched.

Because the general aim of drills and exercises is to learn lessons in order to improve future practice, one of the most important aspects is the real-time evaluation process. The group of observers needs to be trained and forms need to be developed in order to ensure that they acquire the right information during the exercise.

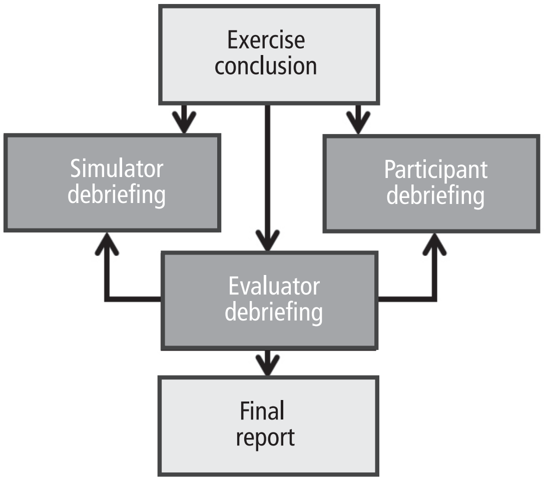

Figure 3 Debriefing and the final report at the end of a disaster drill

Evaluation Processes

The process of evaluation is based on description, deduction, and judgment. Observers need to evaluate actions, not people. They must do so as objectively as possible, without interfering with the course of the exercise, unless there is a safety problem. Evaluation should involve describing the actions taken by players and judging them in relation to the objectives of the exercise. This needs to be done in a spirit of detachment, above all from personal considerations. It is as well to remember that (excepting cases in which safety is compromised) it is legitimate to make mistakes in exercises providing that personnel and organizations learn from them. The evaluators will be called upon to collate their observations and judgments in order to review the progress of the exercise.

It is vital that evaluators do all they can to maintain their objectivity. Tiredness, prejudice, prejudgments, and preconceptions can all threaten this. Moreover, personnel who are under observation may react to the presence of the observer. Nonetheless, evaluators need to avoid being either too lenient or hypercritical. They need to steer clear of bias, distraction, and preconception, and they need to maintain their motivation even after many hours of observation. It thus helps to select observers from among people who have appropriate personalities and experience.

The Final Outcome

The work of the evaluators and the learning experience of other participants need to be distilled into a final report on the exercise (Figure 3). Debriefing should be conducted for each group and perhaps for the entire cast of participants. "Hot" debriefing takes place immediately after the close of play and enables first impressions to be recorded, along with information that might otherwise be forgotten. "Cold" debriefing takes place after an interval of time, perhaps a couple of days, during which the participants have been able to reflect on their experiences. In the debriefing, information is shared, perspectives are compared, suggestions for improvement are recorded, deficiencies are noted, and training needs are identified.

A mass-casualty field exercise in Tuscany, Italy, involving groups of medical responders and the setting up of a field medical post. Frequent disaster drills should be considered crucial for emergency teams, which may have high staff turnover.

The final report should offer a comprehensive picture of the exercise. This includes its motivation, objectives and scope, a description of preparatory activities, and a list of participating organizations. The progress of the exercise should be described, accompanied by an assessment of positive and negative developments. Recommendations for training, improved practice, new equipment purchases, and other aspects should be made. Once again, the purpose is not to incriminate poor performers but to ensure development and improvement of the practice of responding to crises.

In the emergency response field, there is an unfortunate tendency to consider drills and exercises as one-off, unique initiatives. The better strategy, albeit one that is more expensive, is to make these events part of a long-term process of improvement. In this, next year's drill will build upon the results of this year's exercise. Not only does this make the process of learning and improving cumulative, but it also ensures that experience and lessons are not lost, as can happen when there is a high staff turnover or real emergencies are quite uncommon. In summary, disaster drills are memorable, potentially valuable events that can be used creatively to improve the capacity to deal with emergency situations.

Disaster Recovery

Disasters affect people and communities, disrupt societal functions, damage or destroy essential infrastructure, and interrupt economic activity on a scale that means that recovery can take months or years. Recovery strategies typically treat mental health, social, economic, and infrastructure recovery independently. However, effective recovery requires acknowledging their interdependence. For example, mental health and social recovery increase the likelihood of people being available to assist physical recovery and rebuilding efforts and to support business and economic recovery (as employees and customers). Business recovery provides employment and sustains economic vitality. Social and business recovery ensures the availability of a workforce to repair services and infrastructure. This article draws on mental health, social and community, business, and infrastructure recovery to illustrate comprehensive disaster recovery.

Mental Health

In a disaster, ordinary people and emergency workers respond in several ways. Past experience indicates that serious mental health difficulties such as post-traumatic stress disorder are problematic for a minority of people, affecting some 10 percent in major disasters. Other problems include clinical depression, anxiety, or behavioral problems. Some people with preexisting difficulties may find their symptoms exacerbated. However, the more common experience is a transitory adjustment, where symptoms of distress may be common, lower in severity, and relatively short-lived. For this larger proportion of the population, ensuring that their basic needs (food, water, shelter, security, and family reunification) are fulfilled in the immediate aftermath assists their recovery. Training in basic psychosocial support for responders delivering the basic necessities allows them to deliver these in a supportive, enabling way so that those affected can start using their own personal resources to start coping.

Some people may continue to experience a natural reaction of mild to moderate psychological distress in the medium term, despite their basic needs having been met. For this group, a twofold approach is useful. A wide-ranging needs assessment will inform community-led, culturally appropriate, agency-supported psychosocial support activities. These may help families process their experience and adapt to changes in a post-disaster world.

Intervention can reassure people that their feelings are understandable, common, and to be expected given their experience. People should be advised of typical symptoms and reactions (e.g., flashbacks), how they change over time (e.g., anniversary effects), and that the course and time taken to recover differ substantially from one person to another.

Community support is helpful. This can be delivered via individual, family, or group-level interventions that directly address the psychological symptoms for affected persons and those whom they are concerned about (e.g., children, other community members). Children recover well if their routines are quickly reestablished. Returning to their school schedule allows them to keep up learning and to recover in a known, supportive, social environment. Parents are then freed to focus on the myriad tasks they need to address in the recovery phase.

Psychological first aid, delivered by trained personnel, can be useful in this context. For those more seriously affected, or whose difficulties persist for an extended period of time, more specialized, professional services should be made available.

Often, mental health issues become evident later. An attitude of "watchful waiting" can detect many of those requiring assistance, but more proactive approaches should also be prepared. Basic training on common reactions in disaster events is recommended for local general practitioners and teachers who are in the front line of meeting the needs of affected populations. The effectiveness of these activities can be enhanced by integrating mental health and social recovery initiatives.

Social and Community

Social recovery starts with assuming that survivors possess resources and strengths that help them deal with challenges under normal circumstances. Intervention identifies and mobilizes existing strengths and uses bottom-up approaches based upon participation, empowerment, and trust to assist people to apply them in extraordinary circumstances in which usual routines, coping, and support resources have been overwhelmed by the atypical and intense physical, social, and psychological demands presented by the disaster. This process starts by ensuring access to social support.

Social support helps people deal with emotional (e.g., grief, anxiety), tangible (e.g., child care, financial), and informational (e.g., about recovery, assistance programs) issues. If support resources are facilitated by external agencies, they should accommodate local culture, needs, and expectations. A supportive social environment provides the foundation for other social recovery initiatives.

While focusing on strengths, it is important to acknowledge that people and communities possess characteristics that make them vulnerable to experiencing loss and mental health problems. Recovery planning must accommodate both.

Strengths include spiritual and cultural practices, active coping styles, collective efficacy, and community competence. Vulnerability factors include learned helplessness and community fragmentation. In rural communities, vulnerability encompasses, for example, lower levels of resourcing, economic activity more susceptible to disaster-related losses (e.g., agriculture, fishing), agricultural and livestock losses, loss of support systems if entire communities are affected, and rural self-reliance reducing people's willingness to seek or use external assistance.

It is important to appreciate that vulnerability and strength factors coexist. People possess both at any one time. It is how disaster consequences interact with the relative balance of strengths and vulnerabilities that influences the course and nature of social recovery. However, because all people and communities have strengths, strengths represent a starting point for all social recovery activities. Coexisting vulnerability factors should, however, be accommodated in planning and used to predict differential rates of recovery. Focusing on strengths helps all people confront issues in ways that promote natural recovery.

Intervention Objectives

Recovery is built on communicating with communities to clarify what has happened; what is likely to happen over the short, medium, and long term; and helping people identify the strengths and resources they can use to assist their recovery. However, the atypical and challenging circumstances of the post-disaster environment mean that people benefit from guidance on identifying issues and applying their strengths to tackle them. Intervention focuses first on short-term goals.

Focusing on-short term goals prevents people being overwhelmed by the number and magnitude of recovery issues they face from environmental, home, and employment disruptions. It helps people regain a sense of control and allows them to practice using their problem-solving, decision-making, planning, and implementation skills to tackle issues in ways that are more likely to be successful. This helps people build the competencies and confidence to work on other recovery challenges over time.

Recovery planning places considerable importance on accommodating spiritual and cultural values and practices (e.g., rituals and ceremonies) in needs assessment and intervention planning, design, and evaluation. This process can be expedited by working with community leaders. Working with local leadership to accommodate spiritual and cultural practices increases the validity of intervention, empowers communities, builds trust between the community and professional agencies, reduces community dependency on external

Case Study: Recovery After an Earthquake in Canterbury, New Zealand

The earthquakes in Canterbury, New Zealand, from 2010 to 2012 created unprecedented demands on agencies tasked with disaster recovery. An earthquake sequence of this nature and extent in Canterbury was unanticipated, and the multiple agencies involved needed to rapidly coordinate their recovery planning. The earthquake on February 22, 2011, highlighted an acute need to garner a breadth of New Zealand and international disaster recovery expertise to help inform the many facets of a rapidly developing recovery context. To pursue this objective, a Psychosocial Recovery Advisory Group was formed to help support organizations involved in the recovery process. This advisory group reviews and summarizes evidence-based research findings for those who make requests for such information. Extensive experience within the group adds a practitioner perspective to this advice.

The advisory group utilized empirical evidence to underpin the delivery of timely but quality advice. This evidence highlighted the need to provide many levels of intervention, ranging from the general provision of basic living requirements and psychosocial support to specialized interventions for a small proportion of the population suffering from the impact of individual trauma and related difficulties. All advice focused on a psychosocial approach that aims to ease physical and psychological difficulties for individuals, families, extended family (*whanau*), and communities, as well as building and bolstering social and psychological well-being. This entails addressing vulnerabilities as well as looking for and enhancing the strengths of affected individuals and communities, including cultural practices. The broad nature of psychosocial recovery goals demands collaboration between an extensive range of professionals such as psychologists, sociologists, emergency managers, economists, and urban designers.

The group's working definition of psychosocial recovery includes aspects of mental health needs and psychological support alongside communities' capacity to respond and adapt in the face of adversity. This definition also focuses on the importance of community participation and engagement within recovery governance, which has important effects on populations' recovery, resilience, and adaptive capacity. Recovery was understood to encompass individuals and society coping positively with a disaster that has psychosocially and physically changed.

Advisory group collaborations have highlighted practical components of a strength-based approach to recovery: assisting goal setting and problem solving, social support, appreciating cultural and spiritual practices and community diversity, and the importance of coordination and integration.

The advisory group also seeks to advocate the resourcing of integrated monitoring and evaluation that, like other aspects of longer-term planning, could be easily neglected within the ongoing challenges of recovery in the Canterbury region.

The group has focused on maintaining an ability to cooperate and collaborate effectively, building strength from the diversity of member backgrounds and approaches. A recovery process is a vast activity where different perspectives and conflicting needs operate simultaneously. In a disaster recovery situation, these conflicting demands and interests can lead to ineffective dynamics. The advisory group has found a modus vivendi of functioning together to produce documents and support for clients, despite having diverse interests and frameworks. A clear demarcation of roles and processes within the group, along with flexibility when responding to demands, is a factor in developing this efficiency.

An advisory group that can take time to research and reflect, to take a step back from operations to examine and search for pertinent material, can be a positive element in disaster recovery settings.

To date, the group has worked with numerous key agencies, including the Canterbury District Health Board, the Ministry of Social Development, the Ministry of Education, the prime minister's chief science adviser, and the Christchurch Earthquake Recovery Authority. The group has responded to requests by researching and providing evidence-based advice on specific aspects of psychosocial recovery processes and the style and scope of interventions. An advisory group can play a positive role in recovery, beyond the initial planning stages.

resources, helps maintain community identity, and sustains culturally appropriate support systems. Recovery planning should accommodate demographic diversity. Despite experiencing the same disaster, certain groups (e.g., children, elderly people, and people with chronic illness or disability) present unique recovery needs. People who are injured; have lost family members, homes, and livelihood; or been relocated also present unique needs, as do family members living in other parts of the country. This diversity must be accommodated in needs assessment, response planning (e.g., diversity in support needs), and intervention. Social recovery is also dependent on business recovery.

Business Recovery

Business recovery facilitates business survival, protects people's livelihoods, and sustains social and economic vitality in disaster-affected areas. Businesses that sustain their activity or recover quickly can assist recovery for employees (such as by social support) and the community (by providing things like donations of cash, technical expertise, and equipment).

Business continuity (recovery) planning is an important, but often neglected, issue. A survey in 2008 in the United States identified that while 96 percent of senior executives surveyed acknowledged that their business was exposed to natural hazards (e.g., hurricanes, earthquakes), fewer than 20 percent had developed business continuity plans to cover such eventualities.

Businesses must plan to recover from direct (e.g., damaged building) and indirect (e.g., loss of power and telecommunications, damaged roads) interruptions to their activity (e.g., loss of/inability to access premises; loss/damage to equipment, goods, and materials; inability to acquire and distribute goods and materials; employees unable to get to work; and loss of critical data) and changes in patterns of consumption. Affected populations may reduce consumption of nonessential goods and services (e.g., restaurants, cinemas). However, businesses meeting basic and recovery needs can, if prepared, take advantage of increased demand for things like building and infrastructure reconstruction.

Business continuity planning should develop crisis management and information systems and safeguard existing systems (e.g., digital backup and/or substitutes) to facilitate continuity of core business. Recovery planning should accommodate issues such as conducting core operations away from headquarters, dealing with casualties and deaths among staff, and reconciling work and family needs. Plans should be developed in a consultative manner to ensure they are familiar to and accepted by staff, and be linked to training programs and exercises. Collaborative planning provides staff with evidence of organizational concern for their welfare and a shared responsibility for recovery, sustains staff loyalty, and ensures the availability of a supportive culture. The effectiveness of business recovery is dependent on infrastructure recovery.

Infrastructure Recovery

A community's infrastructure, such as roads, electricity supplies, water, and waste water, provides essential services, utilities, and linkages that support day-to-day community activities and represent mechanisms used to respond to and recover from disasters. Many of these functions are vulnerable to disruption and/or damage from a disaster. Because these systems are often large, complex, and interdependent, failure of one part of the system causes impacts in other parts, further increasing a community's vulnerability. Pre-event recovery planning is essential for making systems resilient. Once the vulnerability of a system has been assessed and vulnerable elements identified, mitigation strategies can be developed. Three types of approaches can be used: policy and management measures that reduce the likelihood of damage and/or failure, engineering design measures that reduce the vulnerability, and preparedness and response planning to deal with the consequences of the event. In the recovery phase, the rapid restoration of key infrastructural functions reduces both social and economic impacts and facilitates improved recovery outcomes. However, the initial recovery phase of a disaster is marked by high resource demand, so careful prioritization is needed to balance these competing demands to optimize the benefits to the wider community.

Public and medical services also play key roles in disaster recovery. By managing interdependencies between them and mental health, social and societal, economic, and infrastructure recovery, comprehensive disaster recovery can be facilitated.

Disaster Recovery Life Cycle

Disaster (or emergency) management is typically broken into four main processes (also referred to as phases): mitigation, preparation, response, and recovery. The first two processes focus on reducing the risk from potential future disasters (mitigation) and making plans and structures to deal with post-disaster efforts (preparation). Response and recovery are, respectively, the short-term (e.g., lifesaving) and long-term (e.g., rebuilding) work that begins after a disaster has occurred. The lines between these four processes are fuzzy. Mitigation and preparation often occur simultaneously and are complementary processes. Similarly, response and recovery overlap as the initial response phase winds down and recovery begins. The actors (governments, businesses, nongovernmental organizations [NGOs], churches, militaries, etc.) involved in disaster response and recovery often work to use the momentum for change after a recent disaster to encourage risk reduction, better infrastructure, and improved planning.

Disaster Recovery

The end of disaster recovery is unclear because once a disaster has occurred, the physical and emotional impact on a community can be long lasting and hard to quantify. Disaster recovery begins after the disaster has occurred and there is no longer a consistent threat to life and property, often overlapping with the second half of the response phase. Disaster recovery includes any activity or investment that was made in response to a disaster event to replace, repair, or improve private or public assets. The recovery phase ends when the previous disaster event is not used as the conscious or unconscious reason for any replacement, repair, or improvement activity. The recovery life cycle (RLC) is a step-by-step process that occurs during the recovery phase of disaster management. Here the RLC is broken into seven components that may overlap or even have a different order, depending on the disaster and the people and organizations working with the impacted population and region.

Assessment and Recovery Coordination

Before recovery can begin, it is important for individuals and agencies to identify the state of the impacted community. Typically, a central coordinating body or authority emerges for each geographic area to help ensure safety and continuity of assessment activities in future operations. In cases where the disaster recovery operations are primarily performed by national actors, the government with jurisdiction helps coordinate assessment and recovery activities in accordance with whatever structures or plans are prescribed. Any actors from outside the impacted area are required to conform to local standards and limitations. In cases where a national government is overwhelmed by a disaster or poorly equipped to handle the scope of the recovery operation, the United Nations may work with the national government to perform management and coordination of the impacted areas. Assessment of the damage caused by the disaster and a needs assessment for short- and long-term concerns are performed by many of the actors during the recovery phase, after the primary threats to life and property have been neutralized.

Transitioning Out of Response

Depending on the degree of damage to disaster survivors' property and local infrastructure, it may be necessary to provide transitional housing and services. Transitional housing serves as an intermediate from emergency housing (stadiums, churches, schools, community centers, etc.) provided during the response phase and a return to homes/communities of a "normal" pre-disaster condition. Transitional housing provides a short-term solution to getting communities on a path to recovery by returning public facilities to public function while simultaneously giving survivors space of their own. It is important that transitional housing construction and allocation is equitable and has buy-in from the impacted community. However, provision of such quarters, along with basic water, health, and sanitation provisions, can complicate long-term recovery in the event that the temporary housing is more attractive to survivors than the pre-disaster housing situation. This potential conflict creates a moral hazard where disaster managers must choose which level of amenities and comfort to provide disaster victims that meets needs but also encourages continued progress and locally driven development.

It is important to provide transitional activities for the local populace that generate buy-in for economic and social redevelopment, Schools returning to session, even in a limited capacity, help provide children with daily tasks. Similarly, providing good transitional work is important to help the local workforce gradually return to a productive state, while also avoiding overstimulation in any particular sector of the economy. One key component of the transitional period is the clearing of debris left by the disaster from infrastructure (roads, bridges, waterways, electric grid, etc.) to return them to a usable state, and private property to make way for rebuilding activities.

Rebuilding and Mitigating

Rebuilding is defined as the construction and overhaul of previous and existing infrastructure to the previous state. However, an important aspect of the rebuilding process is when construction projects go beyond merely replacing what was lost, or returning damaged structures to a pre-disaster state, and focus on improving upon the pre-disaster state while incorporating aspects of mitigation into the design and development process. Critical infrastructure reconstruction is important and includes the water/sewage lines, electrical grid, transportation network, and telecommunication channels. Actors involved in the recovery process have taken note of the momentum for real change and risk reduction that often follows a disaster event, and it is important to capture this energy to help improve infrastructure and procedures to reduce the impact of future threats and hazards.

Economic Revitalization

As the rebuilding process gets under way, developing and restructuring the local economy becomes a high priority. It is critical to a successful recovery operation that improvement of the physical infrastructure is accompanied by an economic and social resurgence to fuel continued improvement. This process typically moves to central focus after the basic needs of the population have been met and some sort of shelter and relatively consistent feeding structure is in place. Actors involved in the recovery process may choose to focus on production and purchase of locally produced goods rather than importing necessities and labor from outside the disaster area. Local businesses may rebound with the influx of recovery investment (e.g., restaurants or hardware stores), while local farmers and businesses without a clear disaster niche may attempt to rebuild using government grants and loans, private investment, or insurance payments. The return of economic stability is a long process but is a critical piece of the recovery life cycle.

Local Empowerment

As the recovery process progresses, the presence of external actors in the daily life of the local populace (increase in traffic volume, higher prices for basic commodities, etc.) may begin to become more apparent. However, because external government agencies, private businesses, and other actors have been performing essential services in the disaster-affected area, the transition of control and ownership of the recovery process must make a gradual shift toward locally driven efforts for improvement. External actors may choose to reduce their involvement and hand operations over to local partners or subsidiaries. In some cases this process can take months or years, depending on the culture, level of destruction, and future aspirations of the local populace.

Exit of External Actors From Disaster Area

The eventual exit of external actors from the impacted areas is a significant transition period and a good test of the stability of the revitalized local economy and social will toward improvement. Local businesses that grew up around the recovery effort (construction businesses, etc.) must refocus or move into new arenas of work as the relief money begins to dry up. Insurance money provided to home and business owners tends to have already disappeared by the time the external actors move on. New procedures and mitigation techniques will be tested for the first time to see if they were viable and sustainable improvements upon the pre-disaster state.

The New “Normal”

A new “normal” is developed as the local populace incorporates the past disaster into local culture and customs or ignores the warnings and possible danger. An effective recovery operation should avoid returning a community to its original state without some improvement or alteration to reduce future hazard vulnerability. However, during this stage of the recovery life cycle, the local population is primarily responsible for deciding whether the change in lifestyle, culture, and outlook is worth the cost. Ideally, this is the stage where mitigation and preparation will have reduced the risk from future disasters, and the local community will continue to develop and grow while integrating the lessons of the past.

Disaster Recovery Plan Test Cycle

According to federal information processing standards (FIPS), a plan untested is presumed not to work. Plan testing is not only necessary for the good of the organization but also required by regulatory agencies in most cases. The test offers benefits, though, including a determination of whether the recovery process actually works and whether the alternate site is adequate. It also helps to establish that the assorted teams working on recovery have suitable procedures or that procedures are deficient and team members and managers need additional training. It also provides assurance that the organization really can recover from a disaster.

The events of 9/11 revived interest in planning, with 54 percent of 320 surveyed information technology (IT) professionals responding that the World Trade Center and other attacks would change their disaster recovery plans (DRPs) and 65 percent anticipating a rise in spending on IT disaster recovery. The disaster recovery plan shifted from being a good idea to being an essential one, particularly as management came to see its necessity rather than its expense. Staff and financial shortages and complexity were still deterrents reported in the *Disaster Recovery Journal* survey of May–June 2001. Management commitment comes when managers are made aware of the impact on their business, when risk and outcome analyses are presented in terms understandable by managers, and when managers know that an untested DRP is a virtually guaranteed real-world failure if activated because its assumptions are untested. Like any plan, like any part of business or life, the DRP is not a document but a dynamic process, and it requires regular maintenance and testing.

Limiting Factors

Testing varies according to size of facility, reliance of the organization on IT, user expectations regarding level of service, acceptable downtime and contingency processing time, number of locations included, and costs of testing. Each is a limiting factor.

Disaster recovery is often a paper exercise. Organizations draft a plan, management blesses it, and the paper or electronic copy goes onto a literal or figurative shelf, never to be seen again until time for an update. *Disaster Recovery Journal* reported in 2001 that its online poll of May and June that year indicated that of 2,223 respondents, 65.5 percent had not tested their DRP in a decade, and another 26.32 percent had tested it one to three times in the same decade. The 10 years in question included earthquakes, hurricanes, the Murrah Building bombing in Oklahoma City, the first World Trade Center attack, Y2K, and 9/11. Another study, this by KPMG, indicated that half of DRPs evaluated met an acceptable share of their recovery goals.

Natural disasters such as hurricanes and earthquakes generally encourage businesses to either develop or update the organizational disaster recovery plan. But the plan means nothing if it’s not tested before, during, and after implementation. Testing determines whether the plan is effective or “wallpaper,” so the test must be as carefully developed as the plan is.

Test results cannot be 100 percent certain. That is too expensive, disruptive, and cumbersome, so it is essential to define what business processes to test. Before testing anything, review the DRP list of business-critical processes, determine whether the list is current, and double-check priorities based on business impact analysis and risk analysis (threats, vulnerabilities, safeguards). High business impact analysis (BIA) and risk assessment (RA) scorers are obvious choices for testing. For the less obvious processes, a ranking system based on hard data rather than subjective evaluation is necessary.

Prioritizing

The Business Continuity Institute of London suggests a four-step process of prioritizing: first, isolate testable processes; second, reassess the BIA on a scale of zero to five; third, reassess the RA on the same scale; and finally, matrix the BIA/RA results and, using an agreed-to score as the testing level, select items fitting the standard. If the data are current and the boundaries for testing are management determined, then there is a reasonable set of processes that should be tested.

The plan testing should also involve collateral skills, not just recovery of critical systems. Disaster skills include first aid, competence in breathing apparatus and fire extinguishers, evacuation of personnel and resources, emergency communications, and shutdown for utilities as well as equipment. Recovery personnel need current training or education in these special skills, with multiple competencies when possible. These collateral elements can determine the success or failure of the plan as well as the speed with which it takes place.

That is the easy part. Having determined what to test, the issue is how to test. Constraints at this point include maximum testing of the DRP, costs and service disruptions kept below the prohibitive level, tests actually measuring capability to recover, and test results actually going into the upgraded DRP.

Testing Cycles

Organizations can perform their own structured walk-throughs, checklists, simulations, parallel tests, and full interruptions. They can also incorporate into the plan, if not the testing cycle, the out-of-cycle real-world disasters or problems, an opportunity for ad hoc documentation and incorporation without test preparation. Having established the goals and constraints, the planner next develops a cycle, a phased sequence of tests that employ assorted methodologies, that become increasingly complex as the cycle progresses, that are assessed individually as they occur, and that allow for incorporation of improvement and error correction before the following phase. If the cycle is done properly, it will have tested every aspect of the plan by the time it's done, and it will have tested and updated many portions of the plan several to many times. The test cycle is iterative, so the DRP remains dynamic, always changing as hardware and software change, as configurations adjust, and as business processes change in response to new market needs and service expectations. For the DRP to remain relevant, at the end of each phase or each exercise, there must be a debriefing, audit, and analysis so that the test plan used for the next phase or exercise is valid.

With funding from the Department of Homeland Security Customs and Border Protection, Sandia National Laboratory is fine-tuning an interactive gaming platform (above) known as Ground Truth, which is designed to prepare crisis managers for terrorist attacks.

Limited-scale testing allows correction and elimination of logistical errors that might prove to be major problems in full-scale testing. The DRP testing environment, because it is limited and minimizes cost and disruption to people and products, is a low-pressure exercise that promotes education without duress. The plan cycle becomes part of the work environment, and disaster recovery is something that all workers are prepared for.

Checklists

Checklists are cheap to create, implement, and maintain, suitable for team exercises, and extremely valuable. They are handy for rating key procedures, emergency call trees, adequacy and currency of tape library and operational manuals, and other documentation.

A checklist test allows verification of amounts of supplies at the alternate site, telephone number currency, availability of adequate numbers of forms, and availability of copies of the plan and operation manuals. The team examines the plan for key elements, then uses the checklist to make sure the organization has all those elements.

Walk-Through and Tabletop Exercises

Walk-through exercises are an opportunity for team members to go through the plan-specified steps to identify bottlenecks, gaps, and other shortcomings and to determine the adequacy of the entire sequence. Checklists are useful in walk-throughs once the checklists are validated. The walk-through brings in more people, more knowledge, and more experience, and it familiarizes more staff with DRP procedures, equipment, and off-site facilities.

The tabletop is a conference room walk-through, step by step. Tabletops reveal whether team members know what they're supposed to do in the emergency. They also reveal missing and inconsistent information and documentation errors. The combination of checklist and walk-through should suffice to modify the plan before undertaking more ambitious test types.

A tabletop should be built into the cycle every two to three months and take 90 to 120 minutes, with a 30-minute debriefing to follow. A functional test is a simulation and should take 90 minutes to four hours and occur each three to six months. A full-scale test should not last more than two to eight hours and should occur every four months, if not more often.

Simulation

Another element of the cycle is the simulation. Simulations can be done without disruption to the normal operation of the facility. Ideally, a simulation provides vigorous testing of all assets—hardware, software, personnel—as well as communications, supplies, transportation, utilities, documentation, forms, and procedures. Testing of alternate site processing is also desirable. But simulations, for cost and other constraint reasons, will not normally entail major transportation, relocation of equipment, or shutting down of data or communications. Alternatives for measuring these elements are found in validated checklists. A simulation is more advanced than a walk-through or checklist and can occur legitimately only after those tests have taken place and had their results analyzed and validated. Incorporation of lessons learned from earlier exercises or phases is a key component of any disaster recovery plan testing cycle.

Simulation testing pretends a disaster while the organization continues its daily functioning. The scenario should be realistic and appropriate to the purpose and objectives of the test, the type of test used, timing, scheduling, and the like. Simulations can test notification procedures, temporary operation, and backup/recovery. The simulation needs to test hardware, software, communications, supplies, forms, personnel, utilities, transportation, and alternate site. It does not necessarily involve actual travel or movement of equipment or the shutdown of voice or data lines.

The simulation uses recovery sites, backup systems, possibly teams sent to alternate sites, and other resources. Simulations approximate full-scale tests and work best when they incorporate scenarios of various types. They reveal staff issues about who does what.

Parallel Testing

Parallel testing can take place in conjunction with a checklist or simulation. Parallel testing involves using historical transactions against backup files at a hot site or alternate site. If the alternate site reports agree with those of the actual business, then the test is satisfactory. This test is the most advanced and requires incorporation by the tester and test of all previous lessons learned. Parallel testing uses historical transactions against the appropriate backup files, usually yesterday's transactions and backups, at the hot site. If reports at the hot site and home site match, the systems work.

Full-Scale

The least common test is the full-interruption test in which all elements of the DRP are activated at once. It is expensive and probably disruptive to normal operations and must be approached cautiously with full incorporation of all previous-phase lessons learned. Full interruption testing is expensive and should be used carefully, not at critical processing times, and be of a reasonable duration to measure responses.

Enhancing Effectiveness

All tests produce surprises, but the goal of testing is not perfection but the reduction of error, and the cheapest way to reduce the likelihood of error in the advanced tests is to use the checklist and walk-through properly early on.

A test cycle does not require use of all of the advanced methods, but it should include the two lower-level tests—checklist and walk-through—and at least one advanced test.

An effective test cycle requires an effective and broadly skilled team, including management, finance, legal, personnel, security, and the owners of the process being tested. Multiple owners need to be represented for most tests, which tend to overlap systems (that do not run in isolation normally). The actual tests are run by security, safety, and audit personnel.

The output of the testing cycle phases and of the test cycle itself is an audit and analysis for lessons learned and improvement. Each phase is stand-alone for auditing, and the final audit is of the overall test cycle—training, awareness, organization and administration, documentation management, security of vital records, supplier performance, logistics, contracts and agreements, and the overall cycle's structure, content, and activity as well as success or failure of individual elements and the overall cycle.

At the end of the cycle, the test administrator has to verify that the current DRP contains all changes from the cycle and that it is ready for use in planning the next year's test cycle. The management summary must highlight changes due to lessons learned as well as areas where, in a real disaster, crises might have arisen. Management must know the criticality of making DRP part of every individual in the organization, and testing costs should be identified in tangible and hard numbers and budgeted for in the upcoming year.

Test plans must identify the type of disaster for the given scenario, extent of damage, staffing and equipment losses, backup options, recovery capability, and time/duration of the exercise. Responsible personnel should be identified, along with their particular roles. Tests should at first be only partial so that each part is known to be workable before the full test begins. After-hours or weekend testing may be desirable at first to minimize disruptions, but eventually no-notice testing becomes desirable if the organization wants to demonstrate readiness. New or relatively new plans should be tested every three or six months for the first year, followed by semi-annual tests or annual tests, depending on outcomes.

Testers should log events during the test so they can incorporate their findings in the results. Testing has to include feedback to the disaster recovery team about the state of their plan. The team, generally key managers, should evaluate the results and recommendations for change, so the test has to include elapsed times for each activity, amount of work performed, and accuracy of each activity. The plan should be changed based on the test results and become a more workable basis for a more realistic recovery. It should also be cost-effective and efficient, as it provides continual process improvement and better-prepared personnel. Effective testing should incorporate both scheduled and unscheduled testing of partial and total disasters.

For those companies unable or unwilling or unsure, there are contractors who will, for a fee, evaluate and improve the plan. Forsythe is typical in identifying gaps in the plan, such as insufficient recovery capabilities to meet the company's goals, and finding corrective actions. The result of the assessment and correction is that the company has a plan capable of mitigating threat impacts, perhaps preventing disasters altogether. Tests range from the simple to the extremely complex. Testing requires management backing, and it takes time to prepare and carry out a test. Also, tests take money. To work, they have to have a well-developed and structured process, and the process has to be followed from pre-test through the post-test assessments. To make testing more convenient, companies such as SearchDisaster Recovery.com offer templates and guides. The company promises its guide will teach how to conduct the test, whom to involve, and how to create an effective testing strategy. The template is free, and it contains sections on the concept of continuity testing, how to use the template, a glossary, and a section on effective testing strategies.

Conclusion

Beyond the formal cycle, additional testing is desirable. Orientation tests are the introduction; they require no prior experience, they orient new staff, they should occur monthly, and they should last 60 to 90 minutes. Drills test specific functions, need to be done realistically and test actual responses, involve all levels, occur once a month, and take 10 minutes to an hour.

Plans degrade over time because organizational evolution, incorporation of new products, and changes in policy and procedure produce a new environment that the old plan may no longer capture or measure. The plan has to remain current regarding hardware and software and other key equipment. And planners have to consider personnel turnover as well as forgetfulness or disinterest in the plan if it's left idle too long.

Disaster Risk Reduction

Over the last several years, disasters and their impact on lives, property, livelihoods, culture, and the environment have continued to increase. This includes both human-made and natural disasters.

One of the more commonly referred to definitions for disaster risk reduction is the one used by the United Nations agencies including the United Nations International Strategy for Disaster Reduction (UNISDR) and the United Nations Development Programme (UNDP): "The conceptual framework of elements considered with the possibilities to minimize vulnerabilities and disaster risks throughout a society, to avoid (prevention) or to limit (mitigation and preparedness) the adverse impacts of hazards, within the broad context of sustainable development." It is the approach used to help limit disasters and keep their impacts from occurring. In short, disaster risk reduction includes the various actions related to reducing disaster-related risks and their adverse impacts through a systematic process of analyzing and managing the causes of events and what makes them disasters. This typically includes avoiding/preventing hazardous events from occurring as well as reducing the vulnerability of those exposed to these hazards and increasing preparedness and mitigation measures.

Disaster risk reduction has been gaining broader awareness and acceptance by international agencies, governments, disaster planners, and civil society organizations. This includes its importance as a tool for addressing disasters and development and humanitarian aid, as it is being understood that disasters do not need to occur as they have been, as events become disasters where people, property, heritage, and other elements are exposed to and vulnerable to these events.

One of the reasons that increased attention to disaster risk reduction is being recognized as a means to minimize disasters goes back to the United Nations World Conference on Disaster Reduction (WCDR) held in 2005 in Kobe, Japan, just days following the 2004 Indian Ocean earthquake. At this conference, it was seen that disaster risk reduction was needed, but it was also seen that a strategic framework for implementing disaster risk reduction projects needed to be defined to push international organizations as well as national governments beyond the inexplicit rhetoric typical of most policy statements and toward establishing defined targets and commitments to address disaster risk reduction. The first part of this process was the formal approval at this conference of the Hyogo Framework for Action. This has become the first internationally accepted framework for disaster risk reduction that has been accepted on an international basis and has continued its implementation over the last several years. The Hyogo Framework sets out various objectives (outcome, strategic goals, priorities, etc.). It contains five priorities for actions in order to address the main components needed for disaster risk reduction and is developed in a way that accounts for social, environmental, and economic context from local levels up to national and global levels. These components include the following:

- Making disaster risk reduction a national and local priority and having a strong institutional basis for its implementation,
- Improving risk information and early warning,
- Building a culture of safety and resilience,

- Reducing the risks in key sectors, and
- Strengthening preparedness for response.

Disaster Risk Reduction Planning

There are several steps in the process of developing disaster risk reduction plans. Typically, they include the following:

- Gathering information and data
- Establishing objectives
- Identifying performance criteria
- Understanding hazards
- Developing disaster risk reduction alternatives
- Evaluating and selecting disaster risk reduction options
- Documentation of the disaster risk reduction plan
- Implementation of the disaster risk reduction plan
- Ongoing reviews and updates

Development of Risk Reduction Plans

There are nine phases in the development of disaster risk reduction planning: (1) gathering information and data, (2) establishing objectives, (3) identifying performance criteria, (4) understanding hazards, (5) developing disaster risk reduction alternatives, (6) evaluating and selecting disaster risk reduction alternatives, (7) documentation of the disaster risk reduction plan, (8) implementation of disaster risk reduction alternatives, and (9) updating the plan.

Phase 1: Gathering information and data. The development of disaster risk reduction plans typically begins with gathering information related to the people, location, hazards, vulnerabilities, and project. Information that can help with the establishment of the overall context of the disaster risk reduction assessment may include some of the following:

- Stakeholders involved
- Culture/social environment
- Hazards
- Vulnerabilities
- Regulatory environment
- Overall resources: personnel, capital
- Emergency response characteristics
- Operational/functional characteristics
- Schedule

Phase 2: Establishing objectives. The overall objectives should then be defined. These typically reflect the common goal or mission of the various stakeholders involved from top to bottom, as each stakeholder likely possesses different objectives. Objectives can be defined in a number of ways, depending on the intention of the disaster risk reduction assessment and what the prevention and mitigation measures are supposed to accomplish. Disaster risk reduction objectives may relate to further understanding how various entities may be impacted by a disaster. These, for instance, may be further broken down into people (public, emergency response teams); property (site, contents, structure, collections, etc.); continuity of business operations and limiting downtime; protecting cultural heritage; and limiting the impact to the environment before, during, and after the event. When defining these objectives, one can also define objectives as to how management, mitigation, and prevention measures can be implemented, for instance, limiting the aesthetic impact to a historic structure from seismic bracing, or the installation of fire protection systems.

Objectives are likely not going to be the same for everyone. They need to be developed and fit to each situation in a tailored manner and independent from what may have been done or what worked for other assessments.

One should be cognizant of the potential for competing objectives; objectives for a given situation may compete with each other. These should be appropriately assessed. This may occur, for instance, with security-related and life safety–related matters. For life safety, one needs to try to contain heat and smoke while at the same time enabling occupants to exit and emergency responders to enter; simultaneously, security objectives are looking to limit access to a building and may even block exits with security equipment (turnstiles, scanning machines, etc.) at entrances and exits.

Phase 3: Identifying performance criteria. Once the stakeholders' objectives are established, then they can be transformed into the more quantitative performance criteria. Performance criteria are thus the "metrics" that need to be developed so one can more quantitatively assess the objectives against potential events and hazards.

In light of this, performance criteria can therefore be defined by means that can be directly calculated or measured. As an example, for a stock trading company this could be stated in terms of maximum allowable downtime. For other types of hazards, performance criteria could be developed in terms of the highest potential flood level.

Phase 4: Understanding hazards. There can be numerous potential events or hazards that exist that could lead to a disaster that a disaster risk reduction plan is to address. There are numerous hazard identification techniques to help one condense the larger set of scenarios from "possible" to "credible" scenarios. This smaller subset would represent more of a primary concern and higher probability, and the hazards that need to be further assessed.

Following the identification of hazards, possible scenarios need to be further developed and defined. These hazard scenarios provide additional information and quantification of specific hazards so that they can be further assessed. In the case of fire, for instance, a scenario may go further by quantifying and detailing the characteristics of ignition, growth of the fire and spread to other objects, reaching a peak heat release rate, the duration of a steady burning period, and then the characterization of the decay, and eventual suppression of the fire.

Phase 5: Developing disaster risk reduction alternatives. Once the hazard scenarios have been developed, then disaster risk reduction alternatives should be identified and developed to mitigate these risks. Disaster risk reduction alternatives may include prevention measures, mitigation and physical protection measures, and regulatory requirements that impact codes of construction or use of lands or construction techniques. These alternatives are often intended to help reduce the physical vulnerability and/or exposure to the particular hazard. For instance, they may include measures related to infrastructure (such as dykes to prevent floods).

There are numerous options available for reducing risks. However, it is important to be cognizant of the previously established objectives. Additionally, one may undertake risk assessments that are intended to help stakeholders make informed decisions as to which specific alternatives would be anticipated to achieve these objectives.

The stakeholders may need to further assess the mitigation measures against the impacts they entail—such as their costs and impact on other elements (such as environmental impacts), as well as what resources are needed and whether it is a long-term sustainable solution—in order to inform decisions as to what is to be done to develop an appropriate path forward. A cost-benefit analysis is often quite useful in assisting with this part of the assessment.

Phase 6: Evaluating and selecting disaster risk reduction alternatives. Following the development of various disaster risk reduction alternatives, it is then necessary to evaluate these alternatives to see whether each appropriately addresses the previously established objectives and performance criteria. The assessment can be a qualitative assessment and/or consist of more detailed quantitative evaluations to help determine the event's probabilities. These assessments can also help gain a further understanding as to the potential damage that may occur.

There are a number of different tools and methods available to assess these. These often range from more simplistic "back-of-the-envelope" calculations through much more complex computer analyses. This may also include assessing historic events or conducting detailed probabilistic studies, including event trees, fault trees, HAZOPS, and numerous other types of hazard and risk assessment tools. Following the assessment of these and a determination of which may meet and not meet the previously selected performance criteria, appropriate alternatives can be chosen for implementation. It is important for the stakeholders to remember that this process is an iterative one and that there may be several disaster-related prevention and mitigation options that need to be assessed against the various events and hazards and the performance criteria. After the analyses are finished, stakeholders have the ability to make more appropriate and risk-informed decisions.

Phase 7: Documentation of the disaster risk reduction plan. Documentation of the process and the results of each task, what led to the chosen alternatives, and how each is to be implemented is a key part of the process. This phase assists in further understanding among the stakeholders as to how the assessment was carried out and documents it for inquiries later and for future developments, as this process is an iterative one, as previously noted. The various assumptions and processes at this time need to be clearly defined, as well as the objectives, vulnerabilities, and hazards. The uncertainties and variability surrounding these assumptions should also be further documented.

Phase 8: Implementation of disaster risk reduction alternatives. A strategy for the chosen alternative starts in part with the plan for implementation of the disaster risk reduction measures and prevention strategy. This implementation strategy needs to include details such as prevention measures, mitigation measures, costs, schedule, and priorities. For example, the basic concepts of prevention strategy may include limiting the hazard from occurring and implementing mitigation measures. For instance, for fire, limiting the hazard would include such concepts as limiting ignition sources by checking electrical wiring, separating combustible materials from ignition sources, frequently removing rubbish, testing and maintaining fire safety systems, keeping procedures for operations such as hot works, and training in fire safety and evacuation. Mitigation measures, on the other hand, may include egress systems, detection and alarm systems, automatic suppression systems, compartmenting of the building to limit fire and smoke spread, installation of equipment for firefighting operations, and protection of the structure to limit premature collapse.

Phase 9: Updating the plan. Noted above was the concept that this approach is an iterative one and is continually ongoing and in need of review and updating as necessary. Thus, it is important to create awareness about the plan; provide appropriate training to the various stakeholders, particularly those working on-site; and also establish ongoing assessments so that new hazards, vulnerabilities, and risks are not introduced or created, and that appropriate disaster-related prevention measures and mitigation measures are in place and properly maintained so that they function appropriately as needed.

Disruption of Organizations

Social organizations cannot function as expected if they are disrupted by crises or disasters. Personnel loss and facilities damage are two common features of organizational disruption. Once a disaster happens, structure and tasks can be two dimensions of understanding the organizational change.

Disruption of Public Organizations

The reason people care about "disasters" is often not because of the hazard agent itself but because of its social disruption dimension. As E. L. Quarantelli, one of the pioneers in disaster research, posited, "a disaster can be identified only in terms of some features of a social occasion, that is, some characteristics of the individuals and groups acting in the situation." Because organization is the basic unit of society, the understanding of organizations' disruption is critical for comprehending the nature of crisis and disaster. Disruption of organizations means that organizations are broken apart or their normal functions are interrupted and cannot operate normally.

In most countries, government agencies or the public sector are the main first responders during major crises. The local community disruptions would restrain the efficiency and effectiveness of quick response. Personnel loss and facilities damage are the most significant disruptions for local government. For example, in the case of the 2008 earthquake in Wenchuan, China, many local government agencies experienced a severe loss of personnel. In Beichuan, one of the most damaged counties, about 20 percent of local officials died in the earthquake. Some agencies, such as the Civil Affair Department and Bureau of Education, lost almost half of their staffs. A similar situation was also observed in the 2011 Tohoku Great Japan Earthquake and Tsunami. The tsunami killed many local community leaders and destroyed government buildings. The town of Otsuchi lost its mayor, seven senior staff, and 31 other municipal employees in the tsunami. In Minamisanriku, the tsunami wave overtopped the community's emergency operation and tsunami warning center while local officials were broadcasting evacuation orders there, and in the end, only 10 staff members survived. The worst case in recent years may be the 2010 Haiti earthquake. Most of Port-au-Prince's municipal buildings, including City Hall, were destroyed. Also, many national public buildings, such as National Palace, the National Assembly, and the Supreme Court, collapsed. Even the headquarters of the United Nations Stabilization Mission in Haiti and offices of the World Bank were totally destroyed. Without enough staff and necessary facilities, neither the local jurisdictions nor the national government were able to respond to the tragedy quickly and effectively.

Even though the public sector could experience a lack of personnel in emergency response, worry about role abandonment or role conflict is not necessary.

"Role abandonment" means emergency first responders would abandon their role as public officials during a crisis, and "role conflict" refers to the conflict between their public roles (such as firefighter) and their private roles (such as husband or father). Behavioral studies after disasters in the last 50 years indicate that the role abandonment phenomenon is rare, but it does happen in some cases, such as Hurricane Katrina. Perception studies that ask people how they might react in hypothetical scenarios tend to conclude that widespread role abandonment will occur, especially in some pandemic situations.

Disruption of Business Organizations

Business organizations are essential for community functioning because they provide products/services, employment opportunities, and taxes. Business organizations would also be devastated during crisis and disaster. For example, in Santa Cruz, California, it was estimated that about 60 percent of the downtown businesses were destroyed or sufficiently damaged to require at least temporary closure due to the devastating Loma Prieta earthquake on October 17, 1989. Also, during the 1993 midwest floods, about 41 percent of the business organizations in Des Moines/Polk County were forced to close for some period of time. Prior studies point out that the lifeline services, especially electrical and telephone services, are key determinants of business continuity. Without electricity service, most companies would have to close immediately; without phone or telecommunications service, they could last for only about half a day.

Conceptualization of Organizational Change

Disaster research pioneers E. Quarantelli and Russell Dynes developed the Disaster Research Center (DRC) typology in the early 1970s to help people understand the organizational response to disasters. This typology is a simple fourfold property space that classifies organizations responding to disaster along two dimensions: tasks and structure. Structure is categorized as old and new, and tasks are characterized as either regular or nonregular, resulting in four types of organized responses to disasters (Table 1).

Table 1 Disaster Research Center typology: types of organized behavior in disasters

		Tasks	
		Regular	**Nonregular**
Structure	**Old**	Type I: Established	Type III: Extending
	New	Type II: Expanding	Type IV: Emergent

The established organizations carry out regular tasks and rely on existing structures during the time of disaster. These organizations, like the police and fire departments, are familiar with emergency response and may have the least disruptions from disasters. The expanding organizations, such as American Red Cross or Salvation Army chapters, are another kind of organization involved in disaster response. They carry out regular tasks but extend their structures to disaster-affected areas with formally trained personnel. Type III is the extending organization, which takes on nonregular tasks with the old structure. These organizations are not expected to take a role in disaster response, but they do perform nonregular tasks during crisis. For example, Walmart helped deliver mass-care materials using its logistics system during Hurricane Katrina. The last type is the emergent organization evolving into a new structure and obviously nonregular tasks. Most of these organizations do not exist before the disaster event they are formed during or after emergencies to fill emerged needs.

Doctors Without Borders

Crises occur across the globe and often without warning. Humanitarian organizations dispatch relief personnel to provide food and to conduct rescue operations after these crises have occurred. Physicians, nurses, and allied health professionals are often called upon to respond to these crises. Journalists are often on the scene to report information about the crisis to the general public. In 1971, a group of physicians and journalists in France formed Médecins Sans Frontières (MSF), or Doctors Without Borders, in an effort to respond to a variety of crises across the globe. The organization operates as an independent group and is supported with donations and volunteer personnel; it is not connected to any government agency. Doctors Without Borders responds to calls for assistance during natural, human-caused, and technological crises. These include floods, earthquakes, tsunamis, cyclones, and famine, much of which is caused by acts of armed conflict. Medical care and pharmacy services are provided for epidemics such as cholera, tuberculosis, influenza, malaria, and tetanus. Although Doctors Without Borders maintains neutrality, it often works to bring attention to the plight of those affected by crisis. This may involve bringing attention to areas facing famine, armed conflict, or the forced relocation of ethnic populations without a country or region.

Organization

The primary organization maintains support offices in over 60 countries and partners with 19 associative organizations, allowing for global coverage. Each country is divided into field offices comprising over 22,000 administrative

A malnourished child waits in a Doctors Without Borders treatment tent in the Dolo Ado camp, near Ethiopia's border with Somalia, July 2011. The United Nations declared a famine in five regions of Somalia by early August. By December, "Malnutrition rates are still very high; this is still an emergency situation," said Voitek Asztabski, emergency coordinator for Doctors Without Borders in the camp. Over 50 percent of children in the camp were suffering from malnutrition at that time, according to the United Nations.

and medical staff. This includes physicians, nurses, radiological technicians, laboratory technicians, surgeons, and mental health professionals. Supportive care is provided by logisticians, water and wastewater treatment engineers, and communications personnel. Epidemiologists, chemists, and pharmacists provide medical care, pharmacy services, and specialized medications in areas affected by epidemics such as human immunodeficiency virus and acquired immune deficiency syndrome (HIV/AIDS), malaria, tuberculosis, cholera, or similar outbreaks. Each site is managed by volunteer administrators who are charged with ensuring that all services run smoothly. Doctors Without Borders works with local physicians and hospitals in order to enhance the quality of medical care instead of trying to replace it. This method increases the likelihood that local agencies will work with the organization to provide the best medical care possible.

Team Medical Equipment

Doctors Without Borders responds to crises using the latest, most advanced medical equipment available. The majority of the medical equipment is designed to be used in the field environment, making it fully transportable and easily moved. This is especially important in areas of armed conflict because the team may be required to quickly relocate in order to protect staff, patients, and equipment. The organization has the ability to provide medical care in mobile sites, temporary sites, and fixed locations such as former hospitals. Equipment includes radiological equipment to conduct X-rays, exam areas, emergency triage and treatment equipment, specialized surgical equipment, laboratory equipment, and mobile pharmacies. Moreover, each site is fully self-supportive with both water filtration equipment and wastewater treatment facilities. Comfort care is provided in the form of free blankets, pillows, and clothing.

Epidemics

Epidemiologists typically work with local public health officials in underdeveloped countries to identify and understand disease outbreaks and provide the most advanced treatments available. The goal is to totally stop these disease outbreaks or reduce them as much as possible. Over 1 million patients received medical care and drugs in 2010. Moreover, Doctors Without Borders vaccinated just under 8 million persons for meningitis globally in an effort to prevent infection from the disease. This has resulted in millions of lives being saved.

Response During Armed Conflict

Armed conflict continues to grow around the world, especially in the Middle East and parts of Africa. Doctors Without Borders provides medical care in these areas without choosing sides. An independent, neutral voice allows the organization to enter countries or areas of conflict whenever other organizations are not allowed to enter. Organizations such as the United Nations, the Red Cross, or the Red Crescent are often prohibited from entering these regions because of their connection to foreign nations including the United States. Because Doctors Without Borders serves as an independent, nonreligious group, many countries do allow them to provide medical care and feeding services, whereas others are not allowed to. Acute and chronic medical care is provided, including wound treatment, prosthetics, and long-term medication. This is especially important in conflict-torn countries where both women and children are often the last to receive any medical care. Doctors Without Borders provides both specialized wound treatment and prosthetics in an effort to make life more bearable. Patients in these war-torn areas are often able to return to a normal, productive life by supporting their families with daily tasks such as the gathering of food at the market, farming, or working outside jobs in the community.

Partnerships

Doctors Without Borders partners with governments as well as the private sector in an effort to gain access to hard-to-reach areas. These groups assist with logistics, transportation assets, communication, and medical care. Site security is also a major consideration, so local governments partner to provide these services. Additional partnerships with major food providers allow Doctors Without Borders to provide high-quality, low-cost meals to those facing starvation. Similar partnerships allow the organization to respond to major crises throughout the world. Agreements with other nonprofit organizations such as Feed the Children and Child Reach International not only reduce costs but also allow for the placement of additional volunteers in these crisis-stricken regions.

Documentation

Documentation is a critical component of effective crisis management. Many private, nongovernmental, and governmental organizations already have standard processes in place to ensure thorough documentation for each component of crisis response and management. Such documentation is important for organizations to demonstrate the steps taken in response to an emergency, disaster, or crisis. These efforts are valuable, not only because they help avoid duplicated efforts or problems with the allocation of resources, but also because such documentation ensures the existence of evidence of what was done should problems arise. The specific documentation or paperwork required by different organizations may vary, but there are a few commonalities, such as documentation of insurance policies and ownership, resource and aid distribution, and the identification and tracking of personnel. Most organizations have requirements in place for crisis management and disaster or emergency response plans to exist prior to an event occurring, as well as specific requirements for documentation that fills particular needs about recording what, when, where, why, and how events took place and who was involved.

Before, During, and After a Crisis

Documentation accumulated before, during, and after an emergency, crisis, or disaster not only helps crisis management deal with the problems raised by that particular event but also helps people to understand the actions that should potentially be taken to respond to future events. Such documentation about preparations for crises, active management during crises, and responses after crises are all essential to good crisis management for ongoing and future events. By keeping clear records of crisis management, individuals involved can ensure that proper steps are taken to prepare for and respond to events in progress, as well as to prepare for and prevent errors in future events.

Some of the documentation that is important for emergencies, crises, and disasters must be developed before an event occurs. Business continuity plans and specific plans for crisis response and management, such as evacuation plans and risk assessments, need to be developed before a crisis happens so that each individual involved knows his or her responsibilities. Having insurance policies in place and up to date before a crisis means recovery can begin more quickly and likely run more smoothly after a crisis. Knowing where financial statements or deeds and ownership papers are before a crisis means that they can be transported safely if evacuation is necessary and accessed quickly as needed.

To maintain communications between employees, organizations often also include contact sheets in their disaster, emergency, and crisis plans. The development of these documents helps create plans to manage crises before they occur, allowing people and groups to be better prepared for such events, and to respond to them more effectively. Documents developed before a crisis should clearly lay out the steps that need to be taken, including what each person involved should be doing to prepare for and respond to a crisis, and clearly identify responsibilities in time of crisis.

During a crisis, ongoing documentation of steps that have been taken and plans that have been made is critical, ensuring that what is needed and what has been done are known to everyone involved. For example, incident report sheets are often used to record information during a crisis. This paperwork is crucial to recording and understanding how the crisis developed, progressed, and was resolved. These records include notes about what steps were taken, who was involved in various decisions and actions, and the end result of these actions. While a crisis is progressing, documentation should include notes not only about steps taken within an organization but also information that has been given to outside groups. It also needs to include what the media has been told and how they have spread that information to the public.

After the crisis occurs, documentation often includes recording the effects of the emergency, crisis, or disaster, such as physical damage done to structures (through written reports or photographs); response efforts during immediate relief operations, such as resources distributed to people affected; and steps taken during longer-term recovery efforts, such as payment of reconstruction expenses. Initial documentation of the damage should happen before repair work begins, although this can wait until after emergency search-and-rescue efforts. Documentation of this work includes a variety of information, such as who was involved, what happened, where it happened, when it happened, why certain steps were taken, and how the process occurred, as well as details describing the situation to make the reasons for these actions clear, if necessary.

In addition to being important for governmental and private organization crisis management, documentation is also important for individuals affected by disasters and allows people in charge of recovery and assistance to better help them. This documentation is up to the individual, family, or group to assemble and maintain, but education by organizations about what kind of documentation disaster-affected individuals need can occur before an emergency, crisis, or disaster. It will help ensure that affected individuals are able to provide necessary documentation and that they receive appropriate aid. The personal documentation that individuals should be encouraged to evacuate with and maintain includes items such as identification, birth and marriage certificates, deeds, medical records, and insurance documents. While the crisis is ongoing, individuals should keep records of costs related to evacuation and reconstruction for potential reimbursement.

Downtime

Downtime is a term that refers to a period of time when functions, systems, or personnel are unavailable. Downtime may be a planned or unplanned suspension of operation typically experienced in areas of technology, industry, and human capital. There are numerous possible causes of downtime and the possibility of significant impacts to businesses, government, and society. Emergency planning efforts include addressing downtime during all phases of emergency management.

The opposite of the term *downtime* is *uptime*. *Uptime* is a term describing the measurement of the length of time a system, machine, or process has been active without experiencing any downtime. During uptime, all critical components of a system are functioning without deficiency. Recovery from downtime can be considered the resumption of uptime.

Planned or Unplanned Downtime

Periods of downtime are often planned as part of a system maintenance schedule or update. This time may also include periods when a system is inactive, or idle, on purpose. Planned downtime is often scheduled during a maintenance window when the impact is negligible or minimal. Planned downtime may also be called voluntary downtime.

Although crises can occur from planned downtime, they are more likely to be a result of unplanned downtime. Unplanned downtime may occur because of human error, equipment or utility failure, or overloading. These periods of time may also be referred to as involuntary downtime. Some entities recognize semi-planned downtime, which the organization itself has not planned but another organization has. For example, a vendor may plan downtime to upgrade software for an organization but neglect to inform the user.

Areas of Downtime and Causation

Downtime is a term used mainly to describe systems of technology, industry, and human capital. Technological downtime is commonly understood to impact networks, servers, and communication systems. Technology seeks to eliminate downtime by providing systems of high availability and fault tolerance. Technological downtime may be caused by utility disruption, software error, hardware, interconnectivity, transmission issues, system limits, or procedural error. The causations of downtime are numerous and complex, but important to the quick resumption of operation.

Industrial downtime is the unproductive blocks of time when functional operation ceases. Many of these are planned downtime for maintenance. However, factories and mechanical production systems experience unplanned downtime resulting from mechanical problems and lack of resources. Disruption in utilities, damage, failure, design, overload, and unknown reasons can also cause unplanned downtime.

Human capital downtime describes time when employees are unable to perform their regular work because of another limitation, including meetings, illness, and strikes. The lack of personnel may be the cause of human capital downtime as well. One area of downtime can cause another system to fail; for example, the downtime experienced in human capital can cause downtime in industrial production or technology. Downtime can also refer to the time when public servants are not actively responding to citizens' calls.

The occurrence of downtime may itself be a crisis event. For example, downtime in technology industries can be an event. Downtime can also cause a crisis event, for example, loss of critical infrastructure. A metropolitan area without power may start a cascading event. Or downtime can occur as a result of another crisis event, such as a natural disaster. Downtime is a roadblock to recovery during disasters, regardless of the reason for its occurrence.

The Impact of Downtime

The impact of downtime depends on a number of factors, particularly the system(s) impacted, time of occurrence, duration, and cause. The composition and significance of the system that is inoperable determines much of the impact of downtime. The greater the size, complexity, criticality, and interdependency of a system, the greater the resulting impact. The time of occurrence of downtime affects the impact, since many systems have periods of variable operation. Any downtime during peak use results in more serious impact. An increase in the duration of any downtime typically increases the overall impact. Finally, the cause of the system failure influences the degree of impact and damage caused during downtime.

These factors determine the scope and the intensity of damage. Downtime is measured as a period of time without operation, loss of uptime, and monetary loss. The impact of downtime can range from negligible to catastrophic. Produced goods have the cost of planned downtime built into the sales revenue; however, unplanned downtime results in increased costs. Industries that rely on 24-hour service or e-commerce typically experience greater loss. Downtime can cause businesses to lose customers and revenue or default on contracts. Other impacts of downtime can include intense emotional reactions to downtime by both internal personnel and external customers. The brand images of a business may be impacted significantly and result in loss of revenue. Finally, the impact includes the cost of recovery—getting the system operational again. Governmental agencies experiencing downtime and seeking to continue operations will be impacted.

Downtime Preparedness and Mitigation

As our world systems and environments continue to expand in complexity, thereby increasing the possible consequences of downtime, the importance of preparedness and mitigation continues to multiply. Downtime can be avoided by identifying and eliminating downtime triggers. Systems should be built with redundancy to avoid the occurrence of downtime. Alternative processes and systems may be in place to enable critical operations to continue during downtime. The risk can be minimized by maintaining the system, using reliable components or technical codes that can check sums or detect error. The early detection and notification of downtime can reduce the duration and therefore the impact of downtime. Contingency and business continuity plans address downtime. Recovery plans include downtime duration reduction and recovery planning.

Drought

Drought is a slow-onset natural hazard characterized by an extended period of deficiency in precipitation in a region. Drought disaster is the natural disaster with the largest number of causalities. The frequencies as well as the intensities of droughts are increased by global climate change and population growth. However, droughts do not necessarily lead to a disaster. A drought disaster is not only caused by the occurrence of deficits in precipitation but also by the interrelation of the climate hazard and a social vulnerability. Precipitation itself can hardly be influenced since the effect of artificial techniques of inducing rainfall is still controversial. Therefore, the economic, social, and political characteristics that render livelihoods of drought-prone populations are the crucial factors that determine the extent of drought disasters. People's vulnerability to drought is determined by the way their livelihoods are influenced by the water deficits of a drought, their coping capacities, their resilience, and their assets.

Drought Definitions

There is no universally accepted definition of drought because many disciplinary perspectives of drought exist. Each discipline incorporates different physical, biological, and/or socioeconomic factors in its definition. A broad definition of drought is a deficiency of precipitation over an extended period of time, usually a season or more, which results in a water shortage for some activity, group, or economic sector. Droughts are classified as meteorological, agricultural, hydrological, or socioeconomic.

Meteorological drought is usually defined by a certain precipitation deficiency over a period of time. The thresholds chosen, such as 50 percent of normal precipitation over a six-month time period, vary by location and according to applications. Hence, most meteorological drought definitions relate actual precipitation departures to long-term average amounts. Meteorological droughts are a normal, recurring feature of climate and occur in virtually all climatic regimes. Meteorological drought definitions solely look at the water supply side.

Hydrological drought is defined by deficiencies in surface and subsurface water bodies, relative to average conditions. There is no direct relationship between precipitation amounts and the status of surface and subsurface water supplies in streams, lakes, reservoirs, and aquifers, because the hydrological system components often are used for irrigation, water supply, hydroelectric power production, canals, and flood control.

Agricultural drought links various characteristics of meteorological drought to agricultural impacts, focusing on precipitation shortages, differences between actual and potential evapotranspiration, and soil water deficits. A plant's demand for water is dependent on prevailing weather conditions, biological characteristics of the specific plant, its stage of growth, and the physical and biological properties of the soil. Agricultural drought is defined by the lack of availability of soil water to support crop and forage growth. This lack is also influenced by infiltration rates and the water-holding capacity of soil. During drought onset, agriculture is usually the first sector to experience drought because soil moisture will normally be the first component of the hydrological system to be affected. Drought events can disrupt food production systems and can be a significant natural trigger for famine.

Socioeconomic drought differs from the other types of drought in that it reflects the relationship between the supply and demand for some commodity or economic good that is dependent on precipitation, such as agricultural goods, livestock forage, drinking water, or hydroelectric power.

Drought must be distinguished from aridity. Aridity refers to a permanent climatic condition of very low annual or seasonal rainfall. Moreover, drought is different from desertification. Desertification is used to indicate a long-term and irreversible process of decrease or destruction of biological soil potential. Nevertheless, drought might accelerate the process of desertification.

Drought Assessment and Management

Measures of drought disaster risk management that are targeted at the livelihood security of drought-affected people can prevent a period of water scarcity from leading to a drought disaster. Although drought vulnerability is not equal to poverty, drought—more than any other natural disaster—in particular affects people with low incomes.

Drought disaster risk management focuses on preventing or minimizing negative effects of droughts. Because the pure drought hazard is almost impossible to influence, measures of drought disaster risk reduction are targeting the vulnerabilities of people to drought. Crucial for minimizing vulnerabilities and strengthening capabilities as well as resilience is a comprehensive understanding of the complex structure and spatial distribution of social vulnerability. This is the core aim of a drought risk analysis. Drought vulnerability is spatially variable, and vulnerable groups are dispersed over space. Various drought risk analyses clearly show that the scope of disparities in drought vulnerability is reaching down to the micro level of households. The drought risk can vary significantly among households and depends on livelihoods, class, gender, age, location, social networks, assets, and other particular conditions shaped by economic, social, and political processes.

The quantification of impacts and the provision of disaster relief are far more difficult tasks for drought than they are for any other natural hazard because drought seldom manifests in visible structural damage. Drought-prone regions should conduct risk assessments to identify the factors and processes leading to drought risk and determine who and what is most at risk to drought. A drought vulnerability profile is an invaluable tool for assessing drought risk and should be completed as part of drought preparedness planning in order to systematically address the most vulnerable people. The risk associated with drought for any region or group is a product of the exposure to the natural drought hazard and the vulnerability of the society to drought. A drought risk assessment is the basis for the identification of suitable measures to reduce the drought risk.

Drug Resistance

Drug resistance refers to the ability of a microorganism, such as a bacterium, virus, fungus, or parasite, to resist an antimicrobial medicine that had previously been effective against it. Drug resistance develops as a result of the use of antimicrobials and can be accelerated by the improper use of antimicrobials, such as failing to complete a prescribed course of treatment or the use of antimicrobials against diseases for which they are known to be ineffective (for example, using antibiotics to treat a virus).

Antimicrobial resistance threatens to reverse the gains made by medicine against infectious disease in the last 60 years and is an international problem that can threaten the lives of patients, hamper the control of infectious disease, and increase health care costs. In addition, as the result of modern means of transportation and the ability of people to move all over the world, antimicrobial resistance is not a problem that can be contained in any one country; instead, movement of an infected person can easily spread drug-resistant microbes from one country to another.

Causes of Drug Resistance

Bacteria, viruses, parasites, and other microbes are living organizations that mutate rapidly and evolve over time; the process of natural selection ensures that the microbes that are best adapted to their environment will survive, and those that are resistant to available antibiotics are thus favored for survival. This evolution is a normal process of nature but becomes a matter of concern in terms of medicine because this process of evolution helps create microbes that are resistant to medicines effectively used against them in the past. Consider the example of a person with a bacterial infection who takes a prescribed antibiotic to combat the infection. Some bacteria will be quickly killed by the antibiotic, but others may have mutated and are resistant to it (that is, the antibiotic does not kill them, or kills them more slowly). If those bacteria survive the antibiotic treatment, they will reproduce and very likely pass the mutation on to their descendants, and in this way a large population of antibiotic-resistant bacteria may be created. When these bacteria infect a new person, existing antibiotics may not be effective in treating this patient, who may suffer serious illness or die as a result.

One of the great success stories of modern medicine is the development of antibiotics such as penicillin, sulfa drugs, and tetracycline to combat common infectious diseases. In the mid-20th century, many believed that modern medicine had conquered formerly dreaded diseases such as tuberculosis and pneumonia, while also bringing common infections such as strep throat and ear infections readily under control. However, as a result of the normal course of evolution, as the use of antimicrobials increased, so did the emergence of strains of resistant microbes. Originally, this was less of a problem because numerous types of antimicrobial drugs were available to treat infections, and if one was no longer effective, a different drug could be substituted. However, continued use and abuse of antibiotics has created a situation in which common bacteria are resistant to numerous drugs, complicating the process of treating patients.

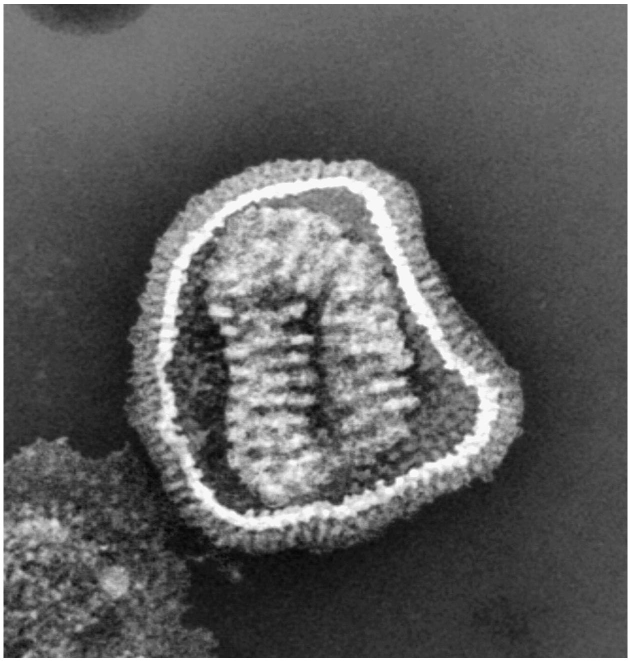
The evolution of drug-resistant bacteria is a natural process, but some behaviors encourage that process. One is failing to complete a prescribed course of antibiotics; this behavior allows bacteria that are resistant to the treatment to survive and multiply. Another is the overuse and inappropriate use of antibiotics; even appropriate use of antibiotics aids the process of breeding drug-resistant bacteria, but overuse and inappropriate use encourages this process without providing any benefit to the patient. Some researchers also believe that widespread use of antibiotics in agriculture (for instance, adding antibiotics to animal feed) also encourages the growth of resistant microbes that can infect humans.

Specific Diseases

Tuberculosis (TB), a disease that once seemed to be nearly conquered by antibiotics, has become a health threat once again because of the emergence of drug-resistant strains of TB. Multidrug-resistant TB (MDR-TB) refers to resistance to the most commonly used (first-line) TB drugs, rifampicin and isoniazid. It can be treated with other drugs, but it has difficulties, including the need for a longer course of treatment and the fact that the less common drugs are generally more expensive and have more side effects than the first-line drugs. The World Health Organization (WHO) estimates that about 440,000 new cases of MDR-TB occur each year, and that at least 150,000 deaths annually are caused by MDR-TB. An even more serious concern is extensively drug-resistant tuberculosis (XDR-TB), which is resistant not only to the first-line drugs but also to any fluoroquinolone and to at least one of capreomycin, kanamycin, and amikacin. According to the WHO, extensively drug-resistant tuberculosis had been reported in 64 countries as of 2012.

Staphylococcus aureus (staph) is a common type of bacteria often found on people's skin and in their noses; however, staph can also cause illnesses ranging from boils and pimples to meningitis and sepsis. When penicillin was first introduced, it was highly effective against staph infection, but today many strains of staph are resistant to penicillin. Other drugs effective against staph have been developed, but a particularly dangerous strain known as methicillin-resistant *Staphylococcus aureus* (MRSA) has become increasingly common and has been particularly identified as responsible for many hospital-acquired infections. The WHO estimates that worldwide, a high percentage of infections acquired within hospitals are caused by drug-resistant organisms such as MRSA and vancomycin-resistant *Enterococci*. In the United States, the Centers for Disease Control and Prevention (CDC) estimate that the proportion of health care-related staph infections related to MRSA increased rapidly from the 1970s to the early 21st century; in 1974, 2 percent of staph infections in intensive care units were caused by MRSA, and this proportion grew to 22 percent in 1995 and 64 percent in 2004. However, increased attention to infection control has caused the number of MRSA infections to decline since then; for instance, a 34 percent decrease in MRSA infections in hospitalized patients was observed between 2005 and 2008.

Shigellosis is an infectious disease characterized by severe and often bloody diarrhea, high fever, and cramping; it is caused by the *Shigella* bacteria. The WHO estimates that shigellosis causes over 120 million cases of severe dysentery each year, primarily in developing countries and in children under five years of age; about 1.1 million people die annually from shigellosis, about 60 percent of whom are children younger than five. Antibiotic-resistant strains of shigellosis are a matter of increasing concern in countries where the disease is common. For instance, a WHO study in several Asian countries in 2000–04 found that a majority of *Shigella* isolates were resistant to cotrimoxazole and amoxicillin, and a 2005 study reported that 95 percent of the isolates of two major strains of *Shigella*, *S. sonnei* and *S. flexneri*, were resistant to tetracycline and cotrimoxazole, and 95 percent of the *S. flexneri* isolates were also resistant to tetracycline and chloramphenicol. The WHO currently recommends only ciprofloxacin for treatment of shigellosis, because of increasing resistance to other antibiotics, but ciprofloxacin resistance is also becoming a problem.



An influenza virus particle. Widespread use of a single medicine could generate a drug-resistant strain of the H1N1 flu virus, but one study has indicated that using a second drug during the early phase of a local epidemic could significantly delay resistance.

Malaria is caused by infection with a parasite transmitted from person to person through the bite of an anopheles mosquito; symptoms include fever and chills, anemia, and flu-like symptoms. Malaria remains a major health threat in many tropical countries; the CDC estimates that 300–500 million cases occur each year, and over 1 million people annually die from the disease.

Drug resistance is becoming an increasing problem with malaria: the WHO found in 2010 that three of the five strains of malaria known to infect humans were partially drug resistant, and some had cross-resistance (resistance to multiple drugs with similar modes of action or that come from the same chemical family) or multidrug resistance. Consequences already recorded for drug-resistant malaria include longer periods of illness, increased mortality, increased cost of treatment, and increased transmission of the disease. In addition, it is feared that ineffective treatment in the public sector (because standard drug therapies fail) will push more patients to the unregulated private sector, where they may be exposed to substandard care as well as a course of treatment known to increase drug resistance.

E

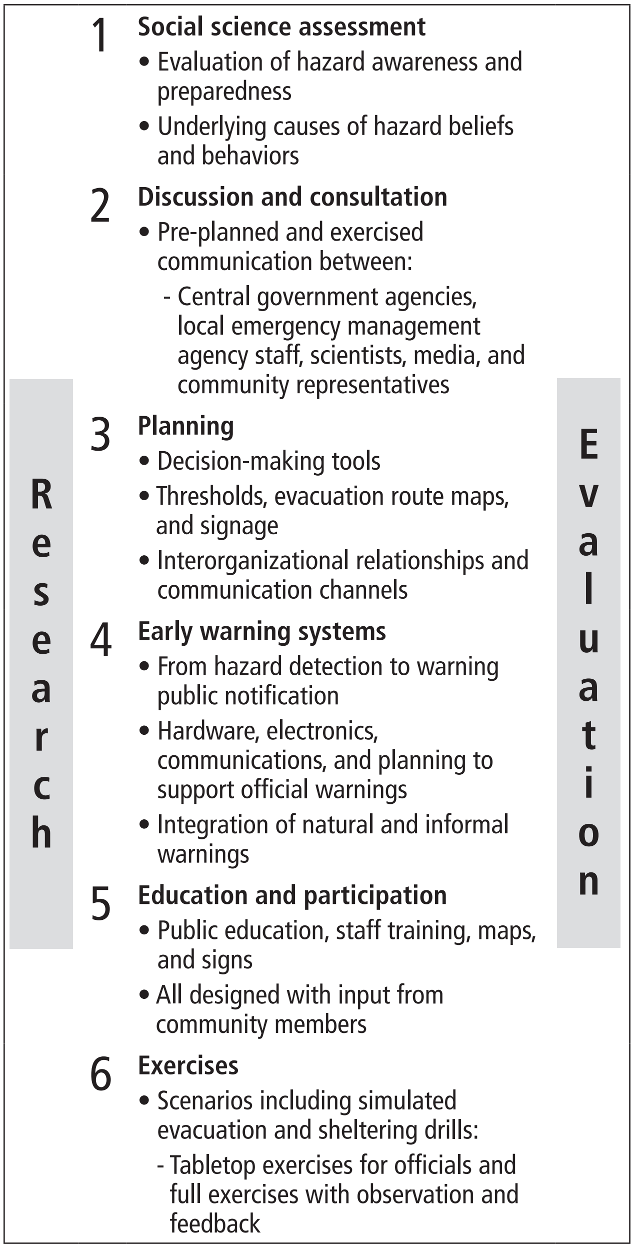
Early Warning Systems

Early warning systems are sometimes referred to as warning systems or emergency broadcast systems. They provide people with emergency information before or during crisis situations so that protective actions can be taken. The phrase *early warning system* (EWS) is often interpreted to mean the technological tools used by scientists to detect threats and communicate information through audible and written channels to emergency managers and to the public. However, EWSs are much more complex. They involve information links between the environment and people and between different groups of people. Information is communicated from multiple sources through multiple channels, ranging from sirens and reverse 911 calls to seeing or hearing cues from the environment. D. S. Mileti and L. Peek describe three basic subsystems of an EWS—hazard detection, emergency management, and public response—yet EWS models focus largely on the first two and much less on the public response subsystem. That is, the models do not accurately reflect the significance of the linkages between people and their observations of the environment and how these observations initiate the warning process and hence response to it. These linkages are, however, well described in the disaster research literature.

Specific elements are required for development of an effective EWS for crisis management. Characteristics of the environment interact with characteristics of society to produce an effective response. The following sections focus on technology used in crisis management, crisis decision making, and interagency relationships, including training and exercises. The case study describes New Zealand's experience with tsunamis from 1960 to 2010.

Early Warning Systems

Traditionally, scientists and emergency managers developed linear models to identify key parties and information channels in EWSs. Models predicted that the flow of information starts when scientists observe a hazard above a threshold (earthquake magnitude). Scientists analyze the data and contact emergency managers to issue an alert if a critical threshold is reached. Emergency managers then make decisions about whether to notify the media and public of the threat and recommend actions. The ultimate receiver of the message is generally considered to be the "public." Such linear models usually misrepresent the warning process in two ways. First, they highlight technology by focusing on the detection and emergency management subsystems, minimizing the public subsystem. This detracts from research findings that the public's first source of information and hence the beginning of response efforts is often human sensory experience with “natural warnings” or “environmental cues” that often precede the hazard (“feeling” ground motion in earthquakes). Moreover, research has shown that people’s first source of warning is often “informal warnings,” received and disseminated through multiple channels (face-to-face contact, cell phones, TV). Additionally, through the use of “social cues,” people look to what others are doing to decide how to respond. Second, warnings meant for and disseminated to emergency managers are sometimes simultaneously received by media and the public. This means that messages are being acted on by the media and public before emergency managers have reviewed a warning and coordinated their response recommendations.



1 **Social science assessment**
- Evaluation of hazard awareness and preparedness
- Underlying causes of hazard beliefs and behaviors

2 **Discussion and consultation**
- Pre-planned and exercised communication between:
  - Central government agencies, local emergency management agency staff, scientists, media, and community representatives

3 **Planning**
- Decision-making tools
- Thresholds, evacuation route maps, and signage
- Interorganizational relationships and communication channels

4 **Early warning systems**
- From hazard detection to warning public notification
- Hardware, electronics, communications, and planning to support official warnings
- Integration of natural and informal warnings

5 **Education and participation**
- Public education, staff training, maps, and signs
- All designed with input from community members

6 **Exercises**
- Scenarios including simulated evacuation and sheltering drills:
  - Tabletop exercises for officials and full exercises with observation and feedback

Figure 1 Model of an effective warning system
Source: Modified after Leonard, Johnston and Saunders, 2006.

Another problem with many EWSs is that responsibility for providing warnings is divided between federal and local government agencies whose mandates are sometimes different. Scientists often have the mandate to provide warnings to emergency management, but recommendations for protective action are the responsibility of local and state emergency managers. This particular division of responsibility for the management of crises requires that warnings or recommended responses are issued at multiple levels of government, at differing times, and by different entities. Predicting social response is made even more difficult when one acknowledges that prior to receipt of official warnings, people are responding to (1) initial natural warnings or environmental cues, (2) informal warnings from each other and the media, and (3) social cues. Moreover, official warning messages are rewritten by numerous government agencies and redisseminated to multiple receivers. This leads to numerous message sources, which has been shown to improve response to warnings by decreasing the time taken to confirm warnings, but this is contingent on the content of the messages being the same. Some argue that there is simply a digital information overload. Furthermore, rewriting messages increases the likelihood of human error in translation, which delays response because people seek additional information to sort out any discrepancies, offsetting the positive effect provided by multiple message sources.

Figure 1 is a model of an effective EWS that underscores the importance of planning and community member involvement in advance of a crisis. The EWS component of the model is placed last to indicate that other factors are equally. if not more. important in outcomes of early warning. Research and social science provide justifications for change and validation of system components.

Technology Use in Crisis Management

The digital age has created a sudden shift in technology available for risk communication channels and the style and content of information. Television, radio, handheld radio, and shortwave radio will continue to be good dissemination channels of information for the foreseeable future, but they are being supplemented by new digital technologies including cell phones, smart phones, Internet, e-mail, social media (Twitter, Facebook), tablet computers (iPad), and online blog sites. Furthermore, new online software allows real-time mapping of at-risk areas, including evacuation routing through programs such as Google Earth. Moreover, some smart phones may serve as mobile scientific instruments capable of detecting seismic ground motion and live data streaming to scientists (iShake project in California), improving spatial accuracy of damage estimates.

Social media have proven an effective platform for coordinating crises. Although they show promise for information exchange and mobilization of resources, little is known about the cyberpsychology that guides people to take protective action behavior. Social networking analysis identifies trends in localized behaviors and offers opportunities to identify where cluster behaviors are likely to occur, allowing emergency managers to intervene.

Crisis Decision Making

During emergencies, response personnel make critical decisions with implications for tens to millions of people. Such situations are often characterized by poorly structured problems, uncertain and dynamic environments, and poorly defined and competing goals across agencies. Moreover, all of this must be done within short time frames and highly stressful environments. In this response environment, decisions involve two distinct steps: (1) a definition of the problem obtained through a situation assessment (SA) and (2) a choice of what to do to protect human health and the environment. SAs identify the primary problem and expected secondary or tertiary fallout. Success requires the correct evaluation of the characteristics of the event, and this involves initial scientific information and the application of standard operating procedures (SOPs), or adaptive and intuitive knowledge that has trained individuals to holistically conceptualize the fallout of the initial conditions and to take appropriate actions. M. R. Endsley considers SA at three levels: accurate perception of factors influencing the environment (spatially and temporally), understanding and comprehension of the real-time situation in relation to desired outcomes, and projection of the status of the event as people meet specific goals.

Organizational decision makers may make correct decisions based upon their perception of the situation, but if their SA is inaccurate, this may negatively influence their decisions about what to do. The second decision-making step concerns the choice of action. This involves (1) recognition-primed and intuition-led action, (2) action based on written or memorized procedures, (3) analytical comparison of different options, and (4) creative, novel design of action. Given the inherent uncertainties often found in crisis situations, the first strategy (intuition-led) has been argued to be more flexible and hence more effective than the others. Effectively implementing such action requires expertise through experience, pre-planning activities, and training to recognize both the situation and the appropriate actions, in addition to accurate SA throughout the crisis.

Interagency Roles

Crisis decision making occurs on individual and team levels. It involves distributed personnel across multiple agencies and geographic and political regions. Effective decision making at this level requires "team situation awareness." According to an assessment by D. Paton and D. Jackson (2002), it is intrinsically related to and dependent upon a team's shared mental model of the problems and tasks at hand. Here, individual team members within and across organizations develop mutual understanding of each other's knowledge, skills, roles, and needs, enabling them to anticipate each other's requests and move from explicit requests to implicit supply of information in communications.

The numerous agencies and their personnel involved in EWSs are essentially members of an extended and distributed team. They range from police, emergency managers, and fire service through to scientific advisers, business owners, and employees. Shared experience among members becomes vital for improving mental models, SA, and their responses. Such characteristics are developed and enhanced through

Case Study: Early Warning and Emergency Broadcast Systems in New Zealand

New Zealand, situated on the Pacific "ring of fire," is susceptible to significant tsunami hazards (see Figure 2 for wave travel times to/from New Zealand). These include tsunamis from local offshore landslides or faults; regionally from areas including the Southern New Hebrides, Tonga, and the Kermadec trench and the volcanoes associated with it and from farther afield, including South America, Cascadia, Alaska, Kamchatka, Japan, and the Solomon Islands. Paleotsunami records indicate there have been at least 15 events in the last 7,100 years that have produced significant tsunamis, with nine of these producing waves of 10 meters or more. Even with this extensive history of tsunami hazard, it was only in 1960 that New Zealand officials began taking note of tsunami risk.

On May 22, 1960, an magnitude 9.5 earthquake occurred in southern Chile, and the absence of a Pacific-wide tsunami warning system in countries beyond the United States meant that the tsunami struck New Zealand without an official warning. Fortunately, there were no New Zealand casualties, mainly because the wave arrived during low tide, but there was significant coastal damage. This event led to significant changes in the way tsunami hazards and risk were managed in New Zealand, notably its membership in the Pacific tsunami warnings system. However, public awareness of tsunami risk and preparedness waned significantly between 1960 and 2004 during a quiescence of tsunamis.

Indian Ocean Tsunami

The 2004 Indian Ocean tsunami led to significant improvements in the political and policy support for tsunami risk management and the human and financial resources to allow the establishment of mitigation measures and improved crisis management capability. In 2005, the New Zealand government mandated establishment of a National Exercise Programme, ranging from regular Tier 1 Local Exercises through Tier 4 National Exercises, to improve the nation's response to tsunamis and other crises. In 2007, a national-level Tsunami Working Group was established. It supported initiatives at local and regional levels as well as improved guidelines for evacuation zones and signage, upgraded warning procedures, and enhanced exercising at national and local levels. However, even with extensive review of national, regional, and local procedures for tsunami crisis management, problems still arose when an magnitude 8.1 earthquake occurred on September 30, 2009, near Samoa. The Ministry of Civil Defence and Emergency Management (MCDEM) implemented its tsunami response procedures, issuing a national warning, activating the National Crisis Management Centre to coordinate the regional and local CDEM groups, and managing media inquiries and public information. Although some actions worked well, a number of problems were identified and confirmed by response to a tsunami warning triggered just one month later from an magnitude 7.8 earthquake on October 8, 2009, in Vanuatu. Post-event reviews identified liaising issues between scientific advisers and MCDEM; a lack of scientific information in advisories, including a lack of information on "what to expect and what to do"; a lack of sufficient staff for media inquiries; and a lack of understanding of which media outlets were broadcasting. Compliance with recommendations had to be established soon after. About this time, a magnitude 8.8 earthquake struck off the coast of Chile on February 28, 2010. Fortunately there had been enough time to implement many of the recommendations that emerged from the 2009 Samoan event, and there was an overwhelmingly positive New Zealand response to the warning.

Exercise Tangaroa

In October 2010, New Zealand had yet another opportunity to test the latest tsunami recommendations and improvements with the implementation of a Tier 4 real-time Exercise Tangaroa, a national test of response to a distant tsunami from South America. These case studies and the evolution of procedures, plans, and warning messages highlight the importance of reviewing previous events to successfully improve future response. It is vital that reviews are conducted in the context of learning for the future, so important recommendations are implemented rapidly, as another event can occur within hours, days, or months. In addition, it is crucial that lessons and the knowledge of tsunami risk be kept a public and official priority through education and exercises. If the 2004 tsunami event had occurred in New Zealand waters, there would also have been widespread devastation and loss of life because the awareness of tsunami risk had declined so significantly since 1960. The unpredictable and infrequent timing of large, damaging tsunamis, combined with increasing density of populations and development in coastal zones, means that nations must continually strive to maintain an ability to manage the inevitability of tsunami crisis.

multidisciplinary planning activities, collaborative exercises and simulations, and a thorough analysis of past performance in exercises and crisis events. Post-event analysis is vital for both large- and small-scale events because it allows identification of whether responses met actual needs. It also helps ensure that a successful response does not lead to an optimism bias whereby people tend to overestimate future response preparedness and capability. This is particularly applicable when a crisis has not recently constituted a major test of response efforts. For example, response to Hurricane Katrina in the United States in 2005 was significantly hindered by differences in the cultures of organizations involved with emergency response and by a lack of interagency trust, before Katrina formed.

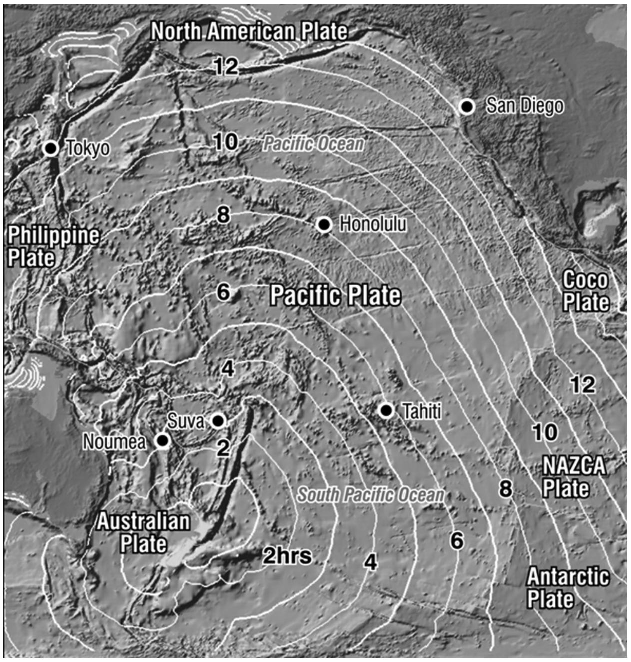


Figure 2 Tsunami wave travel times for New Zealand

Effective communication across agencies is highly dependent on the development of interpersonal and interorganizational trust. Establishment and maintenance of trust requires that teams deliberately work together before a crisis to develop shared mental models. Effective training through periodic exercises supports the development of realistic expectations of operational responses, while also promoting a shared and realistic understanding of decision makers' capabilities for many scales of crises. "Scenarios" should also be used to help ensure that exercises are realistic and have the potential to reduce uncertainty resulting from a lack of understanding of likely impacts and outcomes. Scenarios should reflect investigations of the impacts and of response and recovery issues relating to potential crises. They should adopt realistic timelines and test critical decisions, such as response to variations in hazard thresholds and the fluctuating area of corresponding evacuation zones. This is particularly important for EWSs, when extremely short windows of time for effective critical decisions will be fundamentally dependent upon responders' understanding of their roles, responsibilities, skills, and needs, in addition to those of others.

Earthquakes

Devastating earthquakes strike without warning, surprising the affected population and offering little time to make critical decisions in response to the event. Although disaster mitigation and preparedness planning activities can greatly reduce loss of life and destruction of property, a significant number of people living in earthquake-prone areas still remain ill equipped to respond to and recover from seismic events. In part, lack of preparedness can be attributed to the continued need for populations living in high-risk areas to be constantly ready for an earthquake that may not occur in the months and years to come. However, the 2011 Tohoku earthquake dramatically revealed that even when populations are well prepared, like the Japanese, earthquakes can trigger a cascade of disasters, each with their unique characteristics and demands.

Adoption of an all-hazards model for crisis management, the 2008 National Response Framework (NRF), has been widely promoted by a variety of federal and state government agencies and relief organizations. This type of approach has its merits when responding to several types of disasters that are unfolding simultaneously or sequentially. The NRF includes best practices for managing disasters of any type, severity, and size. Nonetheless, it is important to note that crisis management activities executed during and after a seismic incident differ in significant ways from those planned and performed for a tsunami or a nuclear accident. For example, although evacuation from threatened or affected areas is important for all three types of disaster, unlike the two natural disasters, a nuclear accident has an invisible threat from radiation and requires specific actions for protection and decontamination in the immediate aftermath as well as during the recovery period. In our increasingly complex society, brief earthquakes have the potential to trigger long-term, far-reaching destruction that goes well beyond the collapse of physical structures.

U.S. Seismic Activity and Threat

On average each year, a few thousand earthquakes of varying magnitude take place throughout the United States. Annually, approximately 70 to75 earthquakes occur worldwide that cause significant damage. An earthquake is formed by a series of foreshocks, mainshocks, and aftershocks. The size and duration of the mainshock are indicative of the severity of subsequent aftershocks, which can continue for weeks, months, or even years after the initial tremor.

Specific areas of the United States are noted for their potential for significant seismic activity that would not only result in a large number of deaths because of population density but would also cause extensive damage to the infrastructure, water supply, and transportation system. In the early 1800s, four of the largest earthquakes occurred in the New Madrid Seismic Zone, a seven-state area that encompasses Arkansas, Illinois, Indiana, Kentucky, Mississippi, Missouri, and Tennessee. This area remains at high risk for a catastrophic earthquake and has long been a focus of crisis management endeavors.

The San Andreas Fault is one of several active faults located in California. Researchers, government officials, and the media have centered their attention on northern California, where a megaflood could occur should portions of the 2,600-mile levee system in the Sacramento area be destroyed during an earthquake. If the levees are breached, the supply of fresh water to farms and people living in southern California would be contaminated by saltwater. The adverse effects of a megaflood triggered by an earthquake would reach far beyond California and affect the national food supply as well as the global economy.

Understandably, people living in areas typically not associated with seismic activity are at even greater risk for adverse outcomes during an earthquake. Although there were no reports of major damage or deaths from the 2011 earthquake that shook offices and homes in New York City, Washington, D.C., and Virginia, it was widely acknowledged that people living in those areas are very unprepared for this type of a disaster.

In smaller, more rural communities, there is a new and growing concern about the association between hydrofracking, the process of extracting natural gas from shale rock formations, and earthquake activity in historically inactive areas of the United States. At present, this relationship is poorly understood and is being evaluated by scientists and regulators. A number of government agencies have joined forces to address these varied concerns and to establish sound crisis management programs.

National Programs Planning for Earthquakes

Four agencies constitute the National Earthquake Hazards Reduction Program (NEHRP) Interagency Coordinating Committee (ICC): the National Institute of Standards and Technology (NIST), the Federal Emergency Management Agency (FEMA), the National Science Foundation (NSF), and the U.S. Geological Survey (USGS). To reduce the impact of earthquakes in the United States, the NEHRP agencies collectively gather data on environmental and structural risks for geological disasters and the human responses to such crises. By analyzing outcomes, the ICC works to improve mitigation, prevention, preparedness, education, and disaster response management.

The NIST is the lead agency responsible for coordinating and planning the NEHRP. By conducting earthquake engineering research, the NIST strives to reduce earthquake risk by innovating and updating technical standards for current and future infrastructure in the United States. FEMA educates professionals and communities in emergency management, promotes disaster preparedness, and facilitates post-disaster recovery. FEMA integrates current research in promoting earthquake-resistant building design and in implementing the National Response Plan after an earthquake or other disaster occurs.

The NSF supports a wide range of earthquake research, from early detection of seismic events to development and evaluation of methods for structural and social recovery. The NSF also uses the Network for Earthquake Engineering Simulation (NEES) to create hazardous earthquake conditions for testing structural safety outside an actual disaster. The USGS primarily monitors the status of all natural resources in the United States, including observing and evaluating earthquake activity. The USGS is also responsible for developing and disseminating seismic hazard maps to guide the development of future infrastructure in the United States. In the 2000s, significant progress has been made to coordinate the efforts of federal and state agencies, strengthen mitigation and preparedness practices, and develop effective crisis management programs. However, aging bridges, tunnels, and levees make the United States highly vulnerable to both the short- and long-term consequences of major earthquakes.

Ebola Virus

Ebola virus is one of the deadliest known viruses, and it results in severe acute viral illness, known as Ebola hemorrhagic fever (EHF). The first recorded Ebola patient was a schoolteacher named Mabalo Lokela from the village of Yambuku, Zaire, diagnosed on September 5, 1976. Since 1976, there have been sporadic outbreaks of Ebola in the central African countries. A conservative estimate is that there have been at least 1,800 cases and 1,300 deaths.

Outbreaks

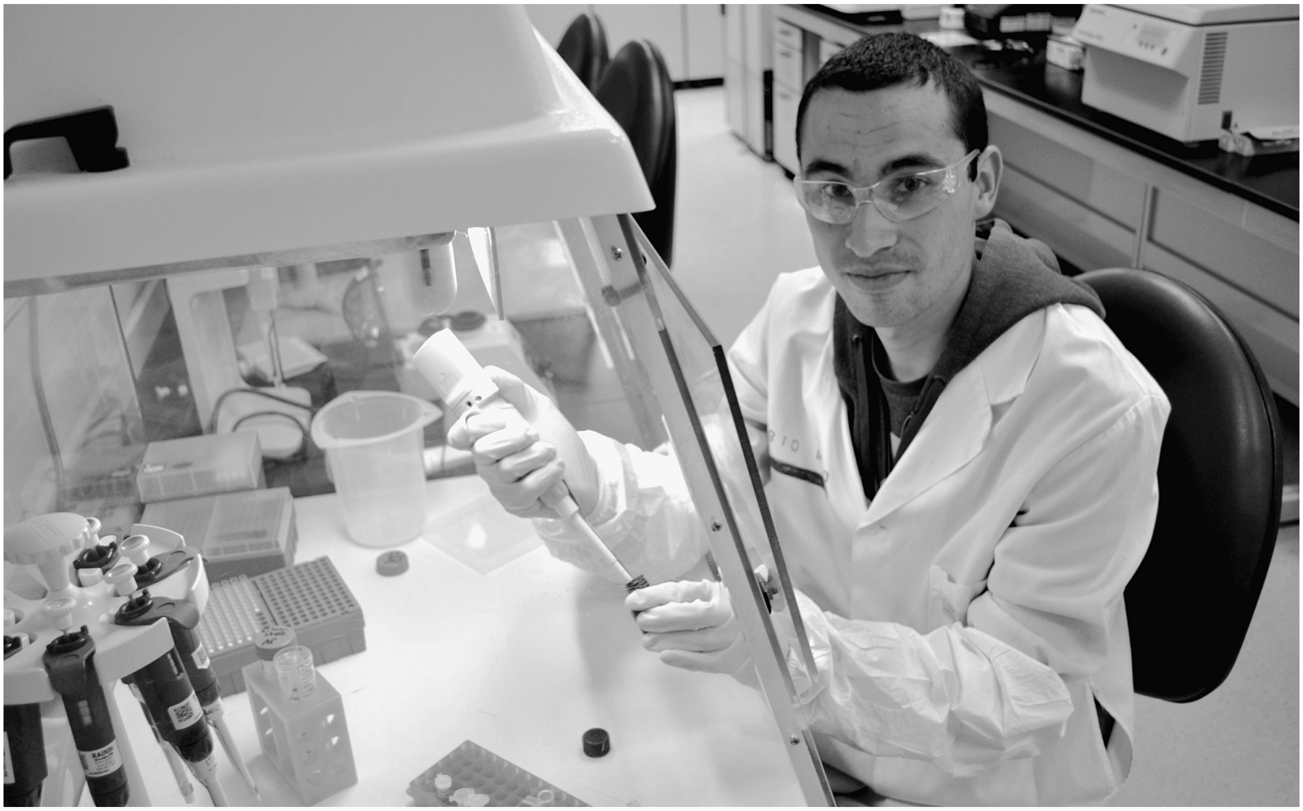
The first documented outbreak of Ebola was in the African countries of Zaire (presently known as the Democratic Republic of the Congo [DRC]) and the Sudan. Both countries had approximately 300 people infected, and the mortality rate was 88 percent in Zaire and 53 percent in Sudan. The Zaire subtype is the most deadly strain. The disease spread was the result of direct contact with the infected, insufficient contamination procedures, and unsanitary hospital practices, such as reusing needles. A second outbreak occurred in both countries in 1977 and 1979. A new subtype was found in Côte d'Ivoire, assumed to have originated from a person dissecting a monkey, in 1994. In 1995, a major outbreak occurred in Kikwit, DRC, where 315 people were infected and 244 died. Three outbreaks occurred in Gabon, in 1994–95, resulting in 98 deaths out of 150 cases. Uganda in 2000–01 had an outbreak of 425 cases with 224 mortalities. In 2001–03, sporadic outbreaks occurred in Gabon and the DRC, resulting in 278 cases and 235 deaths. Another outbreak occurred in the DRC in 2007 (249 cases/183 deaths). Also, in 2007 a relatively mild fifth strain of Ebola was identified in Uganda and is called Bundibugyo.

Classification and Subtypes

Ebola gets its name from the Ebola River in Zaire (aka DRC). The Centers for Disease Control classify Ebola as a biosafety level four, which is reserved for the most deadly and exotic diseases. Ebola virus is listed as ICD-10-CM A98.4 under the International Statistical Classification of Diseases and Related Health Problems (called ICD, for short). Ebola is a filovirus, which belongs to the virus family Filoviridae. There are only two members in the Filoviridae family: *Ebolavirus* and *Marburgvirus*. Both are classified, under the Baltimore classification, as a Group V virus because the viruses possess negative-sense single-stranded RNA genomes. There are five subtypes of Ebola viruses (based on location where they were first identified): Zaire (ZEBOV), Sudan (SEBOV), Côte d'Ivoire (CIEBOV), Bundibugyo, and Reston (REBOV [nonhuman]). The first four were located in central African countries, and Reston is from the Philippines. The first three cause a severe form of hemorrhagic fever in humans, and Bundibugyo is considered a mild strain. REBOV is not known to result in human illness but is fatal to monkeys.

Natural Reservoir

The natural reservoir (host) is presently unknown but is suspected to be a zoonotic virus that lives in the rainforest of Africa and the western Pacific. Even though the infected humans have been linked to nonhuman primates, such as chimpanzees, gorillas, monkeys, and other animals, such as forest duikers (antelope) and porcupines, these are not considered the natural reservoir. It is suspected that nonhuman primates are acquiring it from a different source. Bats are suspected to be a natural reservoir, with evidence pointing at fruit bats as the likely natural reservoir because of having asymptomatic infection of the Ebola virus.



Stanford University student Cesar Ambriz, an intern with the U.S. Department of Homeland Security's HS-STEM program, works on a portable diagnostic test to determine the presence of various viral DNA for organisms like Ebola in biological samples. Most viruses are cultured in a lab, a time-consuming and expensive process. A portable assay with minimal sample preparation could be modified to test for new pathogens and could handle 72 samples in 24 hours, aiding in detection during a bioterrorist attack or suspected outbreak.

Transmission

The chain of transmission has not been established conclusively. It is alleged that the Ebola virus can be directly transmitted from infected bats to humans. Ebola also can be transmitted from the handling of infected chimpanzees, gorillas, monkeys, duikers, pigs, porcupines, or fruit bats (dead or alive). In human populations, Ebola is transmitted by contact with an infected human's blood, secretions, organs, or other bodily fluids (e.g., semen or vaginal fluid) as well as direct contact with the infected person, such as caring for the ill or burials. Nonhuman primates can be infected by respiratory pathway, but humans are assumed to be immune to airborne Ebola virus.

Incubation, Symptoms, and Diagnosis

Ebola's incubation period ranges from two to 21 days. The symptoms during the early incubation period are similar to those of other viral infections, such as aches, chills, diarrhea, fever, headache, low back pain, nausea, sore throat, emesis (vomiting), and weakness. Symptoms in the later stages include hemorrhaging (bleeding) from the eyes, ears, and nose; gastrointestinal hemorrhaging (bleeding from mouth and rectum); impaired kidney and liver function; multiple organ failure; rash (maculopapular) across the entire body, generally accompanied by bleeding; and swelling of the eyes (conjunctivitis) and genitals (labia and scrotum).

The diagnosis of the Ebola virus is confirmed by laboratory tests of blood or serum samples, which identify the presence of antigen or genomic/subgenomic RNA. Specimens collected during severe stages of EHF are the optimal for isolating the Ebola virus. An electronic microscope can confirm filovirions but cannot discriminate between filoviruses, even though they have different lengths. Immunofluorescence assays (IFA) are used to confirm the presence of the Ebola virus via a cell culture, but the results can be misleading. Diagnosis in the field commonly consists of reverse transcription polymerase chain reaction (RT-PCR) used in combination with antigen-capture enzyme-linked immunosorbent assay (ELISA). Testing of Ebola virus is considered an extreme biohazard risk and should be performed under highest biological containment protocols. There have been two laboratory accidents in Russia and one at Porton Down in the United Kingdom involving the Zaire ebolavirus, all resulting in death.

Prevention, Treatment, and Management

There is no cure or vaccine for EHF. Prevention includes practicing strict barrier procedures, isolating the patient, and using new needles. Other prevention strategies include avoiding direct contact with blood and/or bodily fluids, or with deceased EHF patients, and close contact or handling nonhuman primates, duikers, pigs, porcupines, or fruit bats. Treatment consists of providing patients with fluids (intravenous fluids or oral), sustaining blood pressure and oxygen levels, and treating them for any secondary infections. Management of Ebola cases requires identifying the people the patients have interacted with. All hospital staff and first responders need to be briefed on prevention protocols, transmission routes, the lethal nature of the virus, and proper handling of infected persons and soiled clothing and other material.

Ebola as a Bioweapon?

During the Cold War, Russian scientists at Biopreparat experimented with Ebola as a bioweapon. Former First Deputy Director of Biopreparat Ken Alibek hypothesized that Russian scientists may have aerosolized Ebola as a bioweapon. Aum Shinrikyo, a Japanese cult, had a member go to Zaire to collect the virus for use as a bioweapon. However, many scientists consider the possibility of Ebola being used as a bioweapon as unlikely because its lethal nature makes it impractical to transport and it is not known to be airborne.

Electronic Media

Historically, the term *electronic media* was used primarily to distinguish technologies such as broadcast and cable television or radio from print newspapers and magazines; it later expanded to include video games as digital cultural artifacts. In today's convergent media environment, it becomes increasingly difficult to distinguish between "electronic" and other forms of media, as nearly all traditional media outlets also publish at least some content electronically online, and produce content in multimedia formats. The broad category of electronic media now also includes more interactive forms of online communication such as social media and text messaging, as well as institutional Web sites that may contain both static and dynamic content. With the growth of mobile technology, media and communication platforms that rely exclusively or in part on apps for smart phones or tablet devices are also becoming widespread. Electronic media thus encompass a wide variety of content and delivery modes. In the context of crisis management, electronic media constitute means for delivering, broadcasting, receiving, and sharing information throughout all stages of a crisis: before, during, and after. In addition to advantages such as rapid dissemination and extensive reach of time-sensitive or critical information, electronic media also pose additional challenges for crisis managers.

Features of Electronic Media

Studies have shown that different categories of media represent crises differently, so an understanding of different media platforms is important for effective crisis management and communication. Given the complexity of the electronic media landscape, it can be challenging to group media based on traditional nomenclature, such as newspapers, television, radio, and so on. This is especially true with newer formats such as Web sites, mobile apps, podcasts, and social media included under the umbrella term *electronic media*. Instead, it can be more useful to classify media based on four basic dimensions of format, velocity, directionality, and permanence. Format can be classed as text, audio, video, images, or any combination thereof; it can also refer to the relative length of media artifacts. For example, institutional Web pages allow for long documents that may consist of text as well as photographs and embedded video or audio. Podcasts are typically audio recordings, including recorded radio broadcasts, although sometimes the term is used to refer to audiovisual content. Given the decline in real-time audiences for television and broadcast news and the increasing prevalence of mobile devices, the use of diverse formats can allow crisis managers to communicate more effectively with stakeholders.

The relative velocity of a medium indicates how quickly new content or changes can be expected to reach stakeholders or diffuse to other audiences. Multiple electronic media can be used to maximize velocity when necessary. For example, subscription technologies such as really simple syndication (RSS) can be employed to notify subscribers when new information is available and deliver it to a dedicated reader. Social media outlets such as Twitter or Facebook can not only notify followers but also allow them to share links to content with their own social networks. Leveraging multiple delivery modes makes it possible to maximize the reach of time-critical information in a crisis situation.

Some electronic media are designed as one-way communication systems, whereas others allow dialogue. The directionality of a given medium is therefore another factor to be taken into consideration when deciding how, and with whom, to communicate at any stage of a crisis. Social media offer the convenience of rapid information dissemination, but sending messages through these platforms constitutes opening a channel of conversation with users. Crisis managers should be prepared to answer questions and, in some cases, respond to negative comments that can arise when emotions are high as a result of a critical situation (see discussion below of some of the challenges associated with communicating via electronic media, especially online).

Finally, especially in disaster management scenarios, it can be important to provide content that remains available to users for an extended period of time. One of the advantages of convergent media in these instances is that news packages can be archived (often by both the media outlets and the organization or organizations providing important information) for retrieval. Background details, fact sheets, vital instructions, contact information, and other key data should be communicated using electronic media platforms that allow for some permanence of the content. By contrast, conventional radio and television broadcasts are ephemeral, available only to those who tune in to them in real time. Similarly, followers may miss important news communicated via social media platforms such as Twitter, which does not store information long term. Institutional Web sites and media archives are typically the most reliable sites for archiving crisis information.

Trends in Electronic Media

As noted above, the two primary trends influencing the electronic media landscape are convergence and mobile technology. Convergence refers to the increasingly blurred boundaries between media formats: television (or television-like) content can now be accessed not only by means of a conventional television set but also on devices such as desktop or laptop computers, tablets, and smart phones. News organizations typically publish content to online editions of their publications or stations as well as via traditional print, radio, and broadcast outlets, but may also provide text messaging and push notification services for breaking news, deliver headlines via Twitter, and include interactive infographics, audiovisual content, slideshows of photographs or graphic art, and topical collections of links as part of their news packages. Perhaps more important, this array of information and content can be assembled by any organization or even an individual, without the need for highly specialized skills.

Convergence can make it easier for organizations and institutions to provide a wide range of information to media and stakeholders during the various stages of a crisis or emergency but can also dramatically increase the number of competing voices offering the public conflicting information. Convergence also requires organizations to create content in multiple formats to satisfy the technical limitations of various kinds of devices and meet different information needs. See the section below on the advantages and challenges of electronic media for more discussion of this topic.

The rise in mobile technology is creating one of the most dramatic changes in communication, with particular implications for crisis management teams. The ability to report to others directly from the site of a critical event with photographs, video, and real-time accounts can allow effective crisis teams to handle rapidly evolving situations with greater agility. Time-sensitive information can be delivered immediately to the public or to specific stakeholder groups. Those directly involved in, affected by, or observing the crisis as it takes place can also communicate with emergency personnel, volunteers, and the general public.

Within the area of mobile technology, the increasing popularity of augmented reality applications is also of interest for crisis management. Augmented reality consists of a layer of information superimposed over a real-time view of one's surroundings; this content is delivered to users via a special mobile browser. Augmented reality applications can provide background on a location, navigational information, and images of the same location at different times of day or over time. Public institutions and emergency organizations can rapidly update and publish accurate information about an area in the wake of a crisis for use by residents, visitors, or even emergency staff.

Electronic Media

The same features of electronic media that can be used for general classification purposes—along with other distinctive characteristics of the electronic media environment—can represent both advantages and challenges before, during, and in the aftermath of critical situations.

Efficient mass dissemination of messages and information: The ability to make multimedia content available to virtually unlimited audiences with or without the intervention of traditional media gatekeepers, quickly and inexpensively, makes electronic media an extremely efficient mode of communication at all stages of a crisis. However, this efficiency is not equally distributed among stakeholders. During an emergency situation that affects power or telephone service, or in a natural disaster, many people will be without access to radio, television, or online sources of information.

Even during normal circumstances, there are disparities in access to electronic media of all kinds based on geography, socioeconomic status, and overall media literacy, among other factors. It is therefore important to consider who the potential recipients of content may be and develop a multifaceted communication strategy that takes different levels of access into account. Furthermore, the sheer quantity of information to which most people are exposed in contemporary society can make it difficult to garner attention in critical situations; messages should be crafted with this potential obstacle in mind.

Public discourse and conversation: Today's electronic media give extensive reach to individuals and organizations that might previously have struggled to find an audience, and nearly instantaneous indexing by search engines means that anyone can rapidly locate a variety of perspectives on a crisis with relative ease. Crisis managers have unprecedented access to a vast range of discourse, including local news, campus publications, small newsletters, trade organizations, and members of the general public, often even in the early stages of a crisis. This can make it easier to identify and respond to concerns quickly and effectively. For example, in March 2012, after a JetBlue pilot suffering a breakdown was subdued by the crew and passengers during a flight from New York to Las Vegas, forcing a diversion to Texas, the airline was inundated with questions via Twitter and Facebook. The company was able to respond promptly to stakeholder queries and develop a messaging strategy based on its awareness of key areas of public concern.

Archiving: The ability to archive electronic media, both externally and internally produced, is a valuable asset to organizations and institutions in adjusting their crisis management strategies based on careful analysis of past crisis situations. However, the virtually permanent availability of press releases, media coverage, opinion statements, and other crisis-related content can also prove to be a liability in the case of controversial situations or organizations. Information, regardless of its accuracy, can resurface at any time and cause long-term repercussions. For example, links to news reports of a 2006 outbreak of *E. coli* in spinach crops are frequently included in sidebars to media coverage of new food contamination events, organic food regulations, or food safety issues. Spinach sales in the United States have never fully recovered to their previous levels.

Monitoring electronic media: Given the above, crisis managers and communicators need to maintain ongoing awareness of the overall electronic media environment. A number of automated and semi-automated tools can facilitate the task of monitoring, an activity known as "infoveillance": however, a comprehensive environmental scanning procedure should involve people throughout an organization or community who are attuned to potential crises that may emerge from unexpected quarters or that do not match a predefined set of search keywords. The speed and social reach of information (and misinformation) is such that a situation can rapidly devolve into a more severe crisis than necessary if it goes unchecked.

Over the course of a weekend in November 2008, a print and video advertising campaign that the Motrin painkiller brand had launched several weeks earlier caught the attention of a number of mothers who were active in the blogging community. The campaign promoted Motrin as a remedy for mothers' back pain caused by wearing infants in slings. The mocking tone of the commercial sparked the outrage of certain influential "mommy bloggers," which spread so rapidly and widely via social and other electronic media that when the company finally became aware of the situation on Sunday afternoon, it determined it had no recourse other than to recall the entire campaign.

Electronic Vaulting

The emergence and rapid proliferation of e-commerce and Internet-based services have stimulated significant changes in the business continuity and disaster recovery industries. In today's new business venue, ensuring secure and uninterrupted business operations is of paramount importance for both public and private organizations. Sound business continuance requires planning and bracing for all types of business disruption, ranging from human error, power problems, and hardware failures to catastrophic natural disasters and external or internal sabotage or terrorist attacks.

A vital component of business continuity and disaster recovery planning is data storage and backup applications. Among different data backup methods and practices, electronic vaulting is a relatively new technique that is becoming increasingly popular in the disaster recovery industry. Although electronic vaulting has traditionally been used for only high-end solutions, it has emerged as a feasible strategy for enterprises of all sizes in recent years.

Electronic vaulting, also referred to as e-vaulting, is the process of periodically transferring backup data to an alternate off-site location over high-speed networks. Some integral components of electronic vaulting characterize and distinguish it from traditional backup strategies. The main components are (1) offsite data storage, (2) reduced recovery time objective, (3) reduced recovery point objective, and (4) data security and confidentiality.

Offsite Data Storage

A disaster-proof data protection strategy requires that backup data are not only off-line but also off-site and out of reach. However, most companies use their own methods to back up data within their facilities. Although such traditional methods may ensure against minor disruptions caused by technical problems or human error, they are useless in case of a major disaster. Furthermore, on-site backup data is vulnerable to hacker attacks and viruses as well. Therefore, a true data protection and recovery strategy should incorporate an off-site storage component. This strategy makes sure that data are always accessible and up-do-date in at least two alternate locations. Utilizing an off-site facility located at a geographically distant region further ensures against widespread natural disasters.

Reduced Recovery Time Objective

In business continuity planning, the recovery time objective is defined as the maximum tolerable length of time in which business-critical data may be lost in case of a disaster. Traditionally, business continuity plans include a process for data protection in which daily backup data in the forms of magnetic tapes or disc drives are physically transported to a secure facility. This process is called physical off-site vaulting. The recovery process in physical off-site vaulting lasts hours or even days and includes some risks such as damage and loss of data during transportation.

Unlike physical off-site vaulting, electronic vaulting can transfer large batches of data off-site at high speeds and instantly retrieve them in the event of a disaster. Internet-based recovery service provided by electronic vaulting enables organizations to have their systems running in minutes. Therefore, electronic vaulting eliminates the cost, time, and labor required for the multi-day process of transporting backup disks and tapes off-site and bringing them back in the event of a disaster.

Reduced Recovery Point Objective

Recovery point objective refers to the point in time from which the system can restart after a disruption. Depending on the criticality of the data to be preserved, electronic vaulting enables companies to back up data more frequently, which ensures a more current and up-to-date archive off-site. As a result, electronic vaulting significantly reduces recovery point objective and ensures real-time recovery in case of a disaster.

Data Security and Confidentiality

Security and confidentiality of data to be stored off-site by third parties is a significant concern for many organizations, especially for those that want to back up information vital to continuance and even survival of their businesses. Data storage and recovery strategies in which security and confidentiality of data are not ensured leave business-critical data vulnerable to hackers, thieves, and competitors. Encryption is a common solution to these security concerns and a guaranteed method to secure backup data off-site. Electronic vaulting solutions encrypt data at the source before they are transmitted over the Internet to the remote backup site. Data remain encrypted and fully protected throughout their lifetime at the off-site location, and only users with the correct password can decrypt and access them.

The electronic vaulting process is often outsourced to professional and specialized companies. Utilizing advanced telecommunication technologies, these companies offer almost limitless variations on the level of protection and recovery, depending on customer needs and priorities. The banking sector, for instance, where even a few minutes of financial data are extremely important, uses high-end electronic vaulting services to ensure real-time data security. Advantages and benefits of outsourcing the electronic vaulting process include streamlined operations, reduced labor cost, and increased backup and recovery performance.

Electronic vaulting represents a transition from a reactive and separate disaster recovery strategy to a proactive part of the business continuity and contingency planning process. In that regard, electronic vaulting can be seen as another kind of business insurance. With the advancements in data storage technology in recent years, storage hardware prices and the cost per gigabyte to store have significantly decreased. Furthermore, this decreasing trend in data storage prices is projected to continue in the future. Therefore, electronic vaulting today is not a business solution solely affordable for large enterprises. Rather, for small-to-large organizations, electronic vaulting is emerging as a viable technical contingency solution in business continuity plans for all environments.

Electronics Waste

Electronics waste has turned into a waste crisis, representing 8 percent of the global solid municipal waste stream. Mountains of electronics waste (e-waste) are snowballing at rates of over 50 million tons a year. Because much of the waste often ends up in incinerators or landfills, only a small proportion is currently being recycled. Take-back schemes have been introduced in several countries in the European Union (EU) and globally; however, many countries are slow to adopt suitable schemes, and some lack the capacity to deal with the vast quantities that are being generated.

Electronics waste, also known as e-waste, is defined as discarded electronic equipment such as televisions, batteries, mobile phones, and computers. The majority of e-waste can be mined for its raw materials (e.g., copper, gold, and aluminium) and harvested for components. Legal e-waste recycling markets are currently valued at over $6 billion per annum. The soaring rate of e-waste can be attributed to technological advances as old technology becomes obsolete, mass consumer trends, and products nearing the end of their shelf life.

The Basel Convention was agreed to in 1992. It is an international treaty that aims to control the movements and disposal of hazardous waste, including e-waste. Under terms of the convention, it is illegal to export e-waste; however, the growing international black market for electronics waste has led to increasing amounts of e-waste being illegally exported to developing countries under the pretext of a charity donation, or by being wrongly labeled as testing and working when in fact the opposite is true. Readily available processing facilities, low labor costs, and lax environmental regulations and enforcement make shipping e-waste to developing countries such as India, China, and West Africa an attractive solution for unscrupulous traders. As a result, these countries are turning into e-waste dumping grounds. Numerous investigations by environmentalists and regulatory bodies have highlighted that these countries are ending up as e-waste dumping grounds where e-waste is handled in often unregulated and primitive ways. Locals often work in poor and hazardous environments, often with no personal protection against exposure to hazardous components. In an effort to reclaim valuable reusable metals such as copper, gold, and aluminium, methods such as burning and the use of chemicals including cyanide and nitric acid are common.

E-Waste Sources and Problems

Historically, a large majority of e-waste has originated from countries such as the United States, the EU, and China. However, developing countries are experiencing a surge in the amount of e-waste being generated following an explosion in the use of electronics and the continued import of e-waste from other countries. The United Nations estimates that India could experience a rise of 500 percent by 2020 in the number of computers dumped. Implementing e-waste management schemes in developing countries has proven to be problematic for many reasons. Many countries simply lack the infrastructure, investment, and incentive to dispose of e-waste in a safe and environmentally friendly way. The amount of e-waste is growing at such a rate that it is becoming too large to handle. Imports of e-waste from other countries are hampering efforts and leaving developing countries with mountains of waste that are threatening the public health and damaging the environment.

Recognizing a growing environmental problem, Switzerland was the first country, in 1991, to introduce a regulated e-waste program. However, it has been the EU’s Waste Electrical and Electronic Equipment Directive (WEEE), which requires member states to adhere to set collection, recycling, and recovery rates for all types of electrical products and goods, that led the way by introducing the principle of extended producer responsibility (EPR). EPR refers to the mandating of electronic manufacturers to take back products at the end of their life for safe reuse and recycling. EPR follows the rule of the "producer pays" system. It is hoped that this will encourage manufacturers to improve the recyclability of their products by developing more environmentally friendly technologies and reduce the amount of hazardous materials in their products. Despite a global, growing crisis brewing, the uptake of e-waste regulation, with the exception of the EU, has been slow.

Consumers have been slow to recognize the problem that e-waste poses. Consumers' awareness has focused on the use of recover and reuse schemes, thereby preventing e-waste from entering the waste stream and extending the life span of the device. Informing consumers of the correct ways to dispose of their unwanted electronics is seen as a key element in the successful management of e-waste.

E-Waste as a Crisis for Organizations

E-waste can pose a crisis situation for an organization in several ways. The sheer volume of e-waste can increase exponentially, with new technologies constantly evolving. Organizations can find themselves presented with huge stockpiles of out-of-date and unwanted electronic waste. The safe, ethical, and cost-effective disposal of e-waste can prove to be problematic if not implemented or monitored properly. It is important that an organization is fully compliant with local regulations and laws when disposing of its e-waste; this also applies to the contractor tasked with disposal. Before hiring a contractor, it is important that an organization audits and screens its chosen disposal contractor, as improper disposal can have disastrous consequences for both parties, including legal action and negative publicity.

Corporate social responsibility is high on the agenda of many companies that want to be seen doing their part for the environment, and there has been increasing pressure by consumers and environmentalists for companies to adopt environmentally friendly technologies that facilitate effective waste disposal.

The e-waste crisis requires a global solution, and although an increasing number of countries are responding to the crisis by introducing legislation governing e-waste, this needs to be properly regulated and enforced in order for it to succeed. The implementation of EPR, consumer awareness, and clean and efficient recycling facilities are many elements that, combined, can help successfully manage the growing crisis.

EM-DAT

Although hazards, disasters, and crises have been occurring for millennia, it has only been during the past half-century that society has become truly interested in assessing and understanding the multifaceted impacts associated with catastrophic events. The need to systematically track and account for disaster impacts had become the central focus of governing bodies across the globe, yet one centralized repository for all disaster losses has yet to be created. Although there are currently many risk, hazard, crisis, and disaster data sets from which research, academia, decision makers, nonprofit organizations, and the general public can draw information, each has been created for a particular purpose and positioned to answer specific questions. Few among the multitude of data sets are recognized internationally as practical for rationalized decision making. Included here is the Emergency Events Database (EM-DAT) from the World Health Organization's Collaborating Center for Research on the Epidemiology of Disasters (CRED). Originally created to support the CRED and the country of Belgium during the late 1980s, the database has been expanded to cover every country in the world and reports disaster loss and impact information for a variety of events in support of relief and recovery operations, poverty alleviation, and health integration in disaster prone areas.

EM-DAT Aims and Attributes

The main goals of the EM-DAT product are decision support for disaster and crisis recovery, hazard mitigation, and as a means by which international aid contributions to disaster areas can be tracked and analyzed. This decision support requirement is met through systematic collection and analysis of disaster impacts on vulnerable populations across the globe. The EM-DAT has been a leader in creating best practices for disaster data collection, database standardization, validation, and analysis and has created a freely available and accessible Web portal from which disaster loss data can be culled. Specific to the EM-DAT is the differentiation between two generic disaster category types: natural and technological. Within the natural disaster category, users will find five subgroups: Geophysical (earth movements), Meteorological (precipitation events), Hydrological (flowing water), Climatological (temperature extremes, drought, and wildfire) and Biological (epidemics). These subgroups are further divided into 12 disaster types and 30 subtypes.

The CRED implements a stringent set of screening criteria beyond the use of classifications in its acceptance of an event into the EM-DAT database. Specifically, a disaster is included in the database only if it meets at least one of the following four criteria: (1) that 10 or more people were reported killed, (2) that 100 or more people were reported injured, (3) that the event resulted in a declared state of emergency, or (4) that the event resulted in a call for international assistance. A final layer of quality assurance/validation includes a triple verification check at the disaster type level (hurricane), the country level (each impacted country), and the source level (entity providing the data—United Nations, national government, nongovernmental organization [NGO], etc.). The resulting EM-DAT database reflects a systematic and consistent data collection and storage process containing accurate disaster impact information at the country level, including a unique disaster number for each disaster event; a country identifier; a disaster grouping, subgrouping, type, and subset; a disaster start and end date; the numbers of people killed, injured, and homeless; the number of people needing immediate assistance; and the estimated amount of damage (in U.S. dollars). Some cases also contain additional information such as detailed geographic information, magnitude and intensity information, international response status, the amount of aid contributions (in U.S. dollars), and information on specific sectors impacted.

In addition to the tabular data available at the EM-DAT, a coordinated effort between the CRED and the Global Risk Identification Program (GRIP) has developed and deployed a Web-based tool for visualizing worldwide disaster data collection initiatives (DISDAT). This portal aims to facilitate access to valuable, often perishable, disaster information from a variety of disaster compilation initiatives.

EM-DAT Reach and Influence

Partnerships and collaborations that apply and extend the use of data products are vital to the growth, applicability, and utility of any database product. The EM-DAT continues to foster and synthesize relationships with many entities operating at local, national, and international scales. Its current set of ongoing cooperative efforts includes a working association with the International Federation of the Red Cross and Red Crescent Societies (IFRC) whereby the CRED produces annual disaster impact statistics and analytics of key trends on natural and technologic hazards. Additionally, the EM-DAT is utilized by the Secretariat for the International Strategy for Disaster Reduction (UNISDR). Here, the CRED produces country disaster profiles and supports statistical/analytic advances under way at ISDR. Finally, since 1999, the CRED and the U.S. Agency for International Development (USAID) have partnered on a process to create, validate, and maintain the EM-DAT database, including the creation of a downscaled regional disaster information system (RE-DAT). The reach and integration of the EM-DAT is evident beyond these global efforts and continues to grow synergistically among many other disaster organizations, including the Asian Disaster Reduction Center (ADRC), MunichRe Foundation (MunichRe), the United Nations Development Programme (UNDP), the Global Risk Identification Program (UNDP/GRIP), the Hazards and Vulnerability Research Institute (HVRI), the Office for the Coordination of Humanitarian Affairs (OCHA), PreventionWeb, the ProVention Consortium, and the World Bank.

Emergency, Definition of

The *Oxford English Dictionary* defines an emergency as “a serious, unexpected, and potentially dangerous situation requiring immediate action.” In the field of crisis management, emergencies are events that need a professional response from people who are specially trained and equipped to cope with them. Most emergencies are relatively minor events that can be dealt with in a routine way using resources that are normally available. Minor accidents are typical of such situations. However, a small proportion of them require a qualitative as well as a quantitative change in how situations are managed. These “mass emergencies” include major incidents, disasters, and catastrophes. They are defined by scale, severity, and functional changes in working practices.

It is evident that not all emergencies are disasters, but all disasters are emergencies, as the latter is a much broader and less restrictive term. In major emergencies, normal activities will be suspended in order to devote time and resources to the exceptional activities that the emergency situation renders imperative. These include warning, evacuation, crisis management, mobilization of responders, and monitoring of developments. The objectives of emergency management are to make the best use of available resources, to save and protect lives, to limit damage to property, and to facilitate the process of recovering from an incident or disaster.

Emergencies can occur either as a result of cumulative processes or as the materialization of a sudden threat. Regarding the former, environmental degradation is one process that can occur slowly, perhaps imperceptibly, but once it passes a threshold defined by the gravity of its consequences and difficulty of repairing them, it becomes an emergency. Regardless whether the crisis is a slow-onset or abrupt one, there is usually a need to recognize formally that it has reached emergency proportions and make a decision—possibly a declaration—to begin work in an emergency mode. This involves the suspension of normal activities and assignment of most personnel to tasks defined by the emergency, such as lifesaving activities. The success with which the emergency is managed (i.e., brought under control) depends on command processes, resource levels, and the efficient use of appropriate expertise.

It follows that an emergency is a transient event with a definable beginning and end. It is likely to follow a series of phases (Figure 1). The first of these may be characterized by isolation, in which an impact has occurred but help and assistance are not yet forthcoming. Well-organized crisis management services with good plans know how to minimize this phase by careful monitoring of developing situations and prompt, appropriate reaction. The second phase is one of consolidation. This begins with a large "convergence reaction," in which response units come to the affected area and start work. For life-threatening situations in which people are trapped or injured, it is vital that the responders arrive within minutes or hours and that they reach maximum operating capacity as quickly as possible. In all emergencies, response organizations will probably need to expand their activities and work at or near full capacity.

The consolidation period may merge into phases of recovery and investigation, which will in turn merge into the long-term aftermath in which survivors attempt to rebuild their lives, livelihoods, and physical environments. The recovery phase involves restoring a situation characterized by safety and security, and ensuring that hazards have been abated. The investigatory phase becomes important when "perishable" information needs to be collected, for example, on failures, criminal acts, or cases of negligence. Where culpability needs to be proven, as in terrorist outrages or failure to observe laws, then the site of the emergency is also a "scene of the crime" and responders are charged with disturbing the evidence as little as possible.

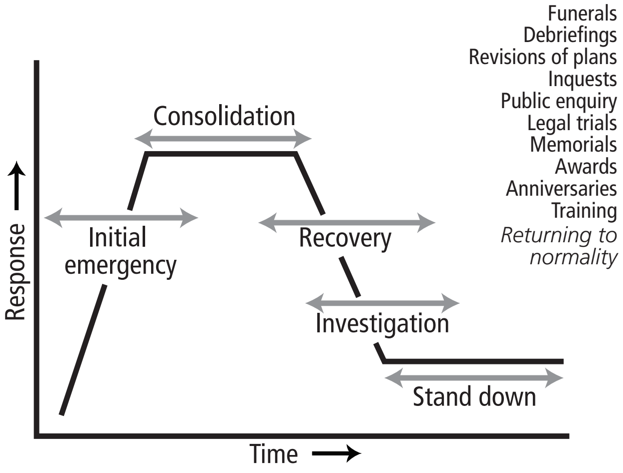

Figure 1 Phases of an emergency

The duration of an emergency depends on several factors. The first of these is the duration or frequency of the causal phenomenon. For example, whereas an earthquake will probably be over within one minute, it may cause entrapment and homelessness that prolong the emergency for days or even weeks. In the days after the main tremors, dangerous aftershocks can exacerbate risk and damage in such a way as to create secondary emergencies. The second determinant of the time scale of an emergency is the ability to respond to it and abate the causes. For example, evacuation is one of the most effective ways of protecting people from violent hazards, but it is only practicable if it is well planned and can be carried out in a safe window of time. Ill-judged evacuation can put people unnecessarily at risk and thus contribute to the state of emergency.

State of Emergency and Emergency Powers

Typically, when a state of emergency is formally declared, responders move immediately into a mode of working that is quite different from their routine activities. Hospitals may be cleared of normal patients in order to receive mass casualties. They may call in extra staff and block routine surgery and diagnostic activities. Emergency operations centers may be opened or obliged to work in a special mode of readiness. Routes may be sealed off, citizens evacuated, cordons set up, and special rules imposed. In democratic societies, it is important that emergency declarations not be used as a cover for abuses of power. Hence, it is vital that the state of emergency be rescinded as soon as possible and normal processes of governance be restored.

Emergency powers may take various forms. They usually involve the temporary suspension of democratic checks and balances, consultation and ratification processes, and normal ways of working on the grounds that all of these are too time-consuming or cumbersome to be appropriate during the emergency, in which decisions must be made rapidly. In effect, the duration of the emergency is defined by the period in which the situation can be managed only by invoking emergency powers, or at least specialized modes of working. Once normal processes can be restored, the justification for using emergency powers disappears.

Emergency Alert Systems

Emergency alert systems (EAS) are mechanisms used to quickly deliver an alert or warning, especially during significant, life-threatening emergencies. These systems are currently used on various scales in multiple settings, including emergency management and monitoring of school performance, among many others.

There is a large difference between early warning systems (EWS) and EAS. EWS are comprehensive risk-reduction mechanisms that encompass four components: (1) risk knowledge, (2) monitoring and forecasting, (3) warning dissemination, and (4) response capacity. In contrast, EAS only cover the warning dissemination component. Even if not as integral as EWS, the EAS are important tools for crisis management. An effective EAS ensures that both threatened people and crisis managers receive a timing alert that allows them to react preventively and protectively before the crisis. This may help save multiple lives and decrease the damages.

National Emergency Alert System

The best-known EAS is the national Emergency Alert System of the United States of America. The system, based on media communications, is designed to transmit emergency alerts to the public at national, state, and local levels. In addition, the EAS enables the president of the United States to address the American public during national emergencies. Each state and several territories have their own EAS plans describing the procedures to deliver state and local alerts to the EAS. Nowadays, three types of alerts are issued using the EAS: alerts issued by the president, alerts involving imminent threats to safety of life, and AMBER Alerts (America's Missing: Broadcast Emergency Response) for child abduction emergencies. Since its implementation, the EAS has been repeatedly used by state and local emergency authorities to transmit emergency alerts to the public, for events such as tornadoes, gas leaks, and child abductions.

The EAS was created in 1994 by the Federal Communications Commission (FCC) and was preceded by two national alerting systems: the Emergency Broadcast System (EBS), created in 1963 during the Cold War and the threat of nuclear warfare, and CONELRAD (Control of Electromagnetic Radiation), a military alert system created in 1951. The EAS is jointly coordinated by the Federal Emergency Management Agency (FEMA), the FCC, and the National Oceanic and Atmospheric Administration (NOAA).

The EAS works as a hierarchical alert message distribution system that involves several communication media called EAS Participants. These include different types of television and radio broadcasters. All EAS Participants are required by the FCC to have EAS equipment installed to be able to transmit EAS alerts. An authorized person at the local, state, or national level may input an EAS alert into the system using the specific encoding equipment. Then, designated highly resilient stations, known as Primary Entry Point (PEP) stations, broadcast this alert to the public in their listening areas. Other EAS Participants monitor the

PEP stations and retransmit the alert to the public in their listening areas. These stations are monitored, in turn, by other EAS Participants. Each EAS Participant or broadcaster must monitor at least two EAS sources. FCC rules also require broadcasters to monitor at least two independent sources for emergency information, ensuring that emergency information is received and delivered to viewers and listeners. This alert transmission system is commonly referred to as a daisy chain.

Following the FCC's rules, messages in the EAS comprise four parts: (1) a digitally encoded Specific Area Message Encoding (SAME) header, (2) an attention signal, (3) an audio announcement, and (4) a digitally encoded end-of-message marker. The SAME header contains information about who originated the alert (the president, state or local authorities, the NOAA, or the broadcaster); a short, general description of the event (tornado, flood, severe thunderstorm); the areas affected (number of counties or states); the expected duration of the event (in minutes); the date and time it was issued (in UTC); and an identification of the originating station. The following attention signal lasts between 8 and 25 seconds, depending on the broadcasting station. Then, the attention signal is followed by a voice message describing the details of the alert. The message ends with three bursts of the "End of Message." In addition to the audio messages transmitted by radio stations, television stations must also transmit a visual message. Scrolling text is displayed at the top of the screen that contains all of the information encoded in the initial SAME header. A color-coded text scroll system is often used where the color signifies the priority of the message.

Integrated Public Alert Network

Nowadays, the EAS is part of a larger and more comprehensive national system of communication called the Integrated Public Alert Network (IPAWS). This system aims to expand the traditional EAS to incorporate more modern technologies including digital systems.

IPAWS is planned to diversify and modernize the EAS, while consolidating all emergency alerts into a single notification system with a common message format. The components of IPAWS include the EAS, focused on radio and television, and the Commercial Mobile Alert System (CMAS), also known as the Personal Localized Alerting Network (PLAN), still in the process of implementation, focused on sending text messages to cell phones and pagers considering specific geographic areas through cell towers. To achieve sending the alert to multiple media, IPAWS will use a new coding protocol called Common Alerting Protocol (CAP), which is in the process of implementation and will replace the SAME. The CAP is a digital text-based message format that uses XML (eXtensible Markup Language) for exchanging emergency alerts. Using the CAP will enable the alert message to be sent through all available means of communication, including cell phones, Internet messaging, pagers, road signs, land lines, satellites, and television and radio.

To help ensure EAS readiness, the FCC mandates that EAS tests be run weekly at the state level and monthly at the local level. The weekly test consists of the header and the end-of-message SAME bursts. The aim of these tests is to ensure operability, identify any potential issues that may arise, and develop solutions to address them on an ongoing basis.

A first national test was attempted on November 9, 2011. The test was aired on every broadcast, cable, and satellite TV station in the nation, as well as every AM, FM, and satellite radio station. But it was not sent to landline or cell phones, pagers, or computers. This is expected to change when the CMAS is fully implemented. Some stations reported that some of their receivers were not able to relay the test. The message may also have lacked the alert code that would allow the president to speak. Because of a feedback loop in the PEP system, the test could be heard several times in the background, and the End of Message code was sent twice, as opposed to three times, violating EAS rules. The test was cut down to 30 seconds from the proposed three minutes.

Criticism and Potential

The EAS has been strongly criticized; the value of a warning system at the national level is especially questioned. Nowadays, the community acknowledges that it has improved much, although there are still many aspects to enhance.

Even if the EAS is improved to ensure prompt message delivery to all concerned people, those people must know how to react appropriately or the system will fail. According to Dennis Mileti, former director of the Natural Hazards Research and Applications Information Center at the University of Colorado at Boulder, for people to respond to the message, it has to include a clear reference to who is the message provider, who must be someone trusted and believed; be delivered over multiple and different communications channels; be repeated frequently; tell people what to do, where to go, which protective actions are required, and when and until when they need to take them; explain why protective action must be taken, telling what the hazard is and what the consequences are from exposure to it; be kept simple, unambiguous, accurate, and authoritative; and finally, be consistent and noncontradictory.

The success of the EAS depends on strong partnerships between alerting authorities and alert disseminators. It is also important that federal agencies work closely in cooperation with state, territorial, local, and tribal governments to ensure this tool is used properly and effectively during extreme emergency situations. Finally, government officials (emergency management), broadcasters, and emergency responders must work to ensure the system is effective, and have local and state plans ready to support protective actions.

Emergency Management, Principles of

Emergency management emerged in the United States following the Cold War era with the intention to protect people from nuclear attacks, but the occurrence of numerous disasters led to creating an emergency management system that is inclusive of all hazards. With increasing numbers of hazards and their severity, emergency management now embraces risk reduction, social vulnerability, and technocratic approaches; it is designed to protect social and physical environments from the impacts of natural and human-made hazards and to aid communities to respond to and recover from disastrous consequences while also preparing to mitigate impacts from future emergency events. Now every country in the world has an emergency management system comprising four phases—preparedness, response, recovery, and mitigation—and eight guiding principles: comprehensive, progressive, risk-driven, integrated, collaborative, coordinated, flexible, and professional.

Emergency Management

An emergency, according to the Webster's dictionary, is a situation resulting from unforeseen events that requires immediate action and attention. Emergency management, as the name suggests, is management of an emergency situation. A disaster is an event disturbing the functions of a community or society, resulting in human, environmental, and financial losses that exceed the ability of the affected community to cope with, using its own resources. The different types of emergencies resulting from a disaster are danger to life, property, and health of people in affected communities, and to the natural environment and ecosystem, for instance, the loss of barrier islands during a hurricane, which act as barriers to storm surge. In

Page Boesl (left) and her daughter fill sandbags at the Sertoma Sports Complex in Minot, North Dakota, June 23, 2011. Using the principle of collaboration, thousands of residents fought the Souris River flood with federal, state, local, and tribal partners.

case of a disaster, emergency management includes all managerial functions responsible for creating a framework within which communities and stakeholders work to cope with the impacts of the disaster and which increase resilience of susceptible and affected communities to future disasters.

Historically in the United States, emergency management originated after World War II in response to the Federal Civil Defense Act of 1950 to address civil defense activities and reduce Cold War tensions. The main disaster that was the focus of emergency management then was threat of nuclear attack. After the modification of the Civil Defense Act in 1958 and following the disasters of the 1960s, especially the earthquake near Hebgen Lake, Montana (1959), and Hurricane Donna (1960), emergency preparedness functions to deal with natural disasters were included with civil defense activities. This led to the creation of a new emergency management concept—a system embracing an all-hazards approach with the goal to protect the public in all kinds of emergencies. Being an all-hazards approach, the current emergency management, as defined by the Federal Emergency Management Agency (FEMA) Higher Education Project, is a risk-based collaborative and coordinated approach implemented by all stakeholders with the intent to protect life, health, property, environment, and economy of communities impacted by a disaster. The mission of emergency management is to aid communities to increase their ability to reduce adverse impacts of a hazard and to increase their resilience and sustainability to prepare for, respond to, and recover from natural or human-made disasters. The current version of emergency management system comprises four phases and eight principles to address the needs of communities in case of a disaster and adapts an integrated/collaborative approach among stakeholders.

Phases of Emergency Management

The four phases of emergency management—mitigation, preparedness, response, and recovery—are linked together in a cyclical manner so that effective and efficient emergency management activities can be implemented before, during, and after a disaster to ensure the impacted communities' return to their life before the disaster occurred. A discussion of the activities and goals of each phase follows.

Mitigation: This phase can happen anytime, as it includes actions to reduce the chance of an emergency happening and the extent of its damaging effects on citizens and businesses. Because the intention is to reduce the devastating effects of an emergency, this phase should be implemented long before an emergency happens. Some of the activities that should be undertaken include implementing structural guidelines/building codes to maintain safety of a structure against fire or hurricane wind/storm surge impact. Such activities include elevating houses beyond the maximum flood limit, buttressing roofs/doors/windows to protect from wind impacts, implementing land use codes to protect future urban growth (e.g., restricting construction in flood-prone areas), and purchasing insurance (fire/flood) to cover financial effects of a future emergency.

Preparedness: This phase, which also happens before an emergency occurs, involves preparation of plans and other activities by emergency management agencies, the general public, and other stakeholders to aid communities in dealing with an emergency situation. Some of the activities in this phase include the following:

- Preparation and implementation of emergency and evacuation plans: these plans help identify actions agencies need to take in case of an emergency. Evacuation plans help identify the best shelters and routes to be used to evacuate people and animals from the emergency impact zone.
- Holding disaster drills and public education: these activities are geared toward communities with the intention to help them understand the sequence of events and actions they have to take before, during, or after a disaster to protect themselves and their families and friends.
- Preparing a disaster kit containing food, water, emergency lights, and other such necessities to help families.

Response: This phase occurs during an emergency. The goal of this phase is to protect lives and prevent damage to properties from a disaster. One major action of this phase is implementing identified preparedness activities during an emergency. Therefore, for the success of this phase, it is required for all agencies involved in this process, from local to federal as well as communities and community-based organizations, to work in a collaborative and coordinated manner. Some of the actions in this phase include:

- Warning and alert: alerting the public, if possible, before the occurrence of a disaster (e.g., warning the public in coastal communities before a hurricane makes landfall so that actions to evacuate in a timely manner to available shelters can be taken, or warning the public during a tornado to take shelter in an enclosed space identified to protect from a tornado, such as the basement of a house).
- Implementing other preparedness actions during an emergency.

Recovery: This phase begins immediately after an emergency or a disaster has ended. The goal of this phase is to help communities get back to their normal routine. Activities in this phase also include building a safer situation after the emergency to cope with changing environments and future events. Actions in this phase include removal of debris, repair and rebuilding of structures/infrastructures, provision of financial aid through insurance companies to help businesses recover as well as impacted citizens to rebuild their structures/get employment, and providing special assistance programs to impacted people to recover from their health and psychological trauma. The duration of the phase can be a few hours (e.g., a roadside accident) to several years (e.g., an event like Hurricane Katrina) to recover from the devastation. However, the longer the recovery phase, probably the more difficult it is for people to get back to normalcy, because the surrounding environment undergoes numerous changes.

Principles of Emergency Management

Principles include underlying guidelines for effective management of an emergency universally. The eight principles of emergency management are as follows:

Comprehensive: A jurisdiction encounters a number of natural and human-made hazards; it is pertinent to identify all hazards and prioritize them based on the likelihood of their occurrence using historical data. Although one set of actions can be used to address any hazards, all hazards are different in their occurrence and impacts, and therefore require different management activities. Identifying all hazards will help in the risk assessment process to prepare plans specific to disasters, including solutions to deal with all possible adverse impacts in all phases of emergency management. The plans should also identify all stakeholders, in both public and private sectors, to ensure coordination and collaboration of actions for effective management of a disaster, for faster response and recovery, and for effective mitigation. Therefore, emergency management should be comprehensive, which means it should take into account all possible implications of all hazards, all stakeholders involved and impacted by the disaster, and all actions to be implemented at all phases.

Progressive: Hazards are becoming frequent, severe in their magnitude, and devastating in their impacts on society and environment. It is therefore pertinent to predict the possible future impacts of a disaster and spatial distribution of impacts to identify vulnerable locations and populations that will need aid so that effective plans and actions can be prepared to mitigate future impacts. These requirements necessitate emergency management to be progressive in its approach so that emergency managers and emergency management actions will be preventive and preparatory to build a resistant, resilient, and sustainable community.

Hence, emergency management now implements a prevention and risk reduction approach focusing on risk assessment and management, a social vulnerability approach focusing on reducing vulnerability and increasing resilience and sustainability of communities, and a traditional approach focusing on management of all hazards.

Risk-driven: The goal of emergency management is to reduce risk to protect lives and properties by using available resources in an effective and efficient manger. Hence, it is required to formulate and establish policies and activities for emergency management based on assessed risk from all possible hazards to locations, people, properties, businesses, and the natural environment. The risk assessment approach is predictive and proactive in nature as it tries to determine potential damages and losses that the social and physical environments will experience from future hazards.

Integrated: Although a disaster and its adverse impacts are local in nature, in order to cope with the emergency situation and increase future resilience of impacted communities, the management actions are shared among private and public stakeholders at every level of government: local, state, tribal, federal, and community. Because of the involvement of so many stakeholders, their participation in the decision-making process at every phase is required to make the efforts more coordinated and effective. Therefore, it is necessary to develop a framework that is both top-down and bottom-up in its implementation and integrates the principles and effective practices between different levels of government and within each government agency at each level to develop an effective emergency management routine that is adaptable to the situation, rather than generic.

Collaborative: Because of the participation and involvement of a number of stakeholders from public and private sectors and the impacted communities, it is essential for the participants to collaborate with each other, which will help emergency managers work as a team by pooling resources for effective implementation of emergency actions. The goal of this principle is to encourage a culture among emergency managers that will encourage trust—a team atmosphere that will facilitate communication and build consensus.

Coordinated: Because of the involvement of numerous agencies and stakeholders with different goals and missions, and headed by different personnel, coordination requires these agencies to agree upon a common mission, that is, effective management of a disaster and its societal and financial impacts. Coordination also ensures that the role of each stakeholder in the overall picture of emergency management is identified and recognized by the emergency managers and all involved stakeholders/agencies/agency personnel. The main goal of coordination is to pull together the available resources of all involved agencies and organize the implementation of emergency management activities by assigning the activities and resources to emergency managers.

Flexible: Emergency management is comprehensive, which means that a one-for-all approach comprising a common set of activities will not be effective and applicable while dealing with a disaster. Likewise, because of the diverse nature of responsibilities of emergency managers and participating agencies/institutions, policies guiding emergency management need to be flexible to allow participants to perform a task suitable to an emergency situation irrespective of the said participant's original task delegation. In a nutshell, the framework and policies of emergency management should allow emergency managers and other participants the flexibility to choose an action and/or policy or devise a creative and innovative activity that is not only problem-based in nature (dealing with a specific disaster) but also place-based (tailored to address the needs and issues of the local community impacted by the disaster).

Professional: Scientific, knowledge-based, and innovative approaches are used to develop solutions/activities to deal with emergency situations and adverse impacts of disasters of communities. It is, therefore, required for emergency managers to have the requisite experience and standards to achieve the final goal of protecting lives, property, and the environment. In addition to having professional attributes, emergency managers must follow a code of ethics, standards and practices, training, professional experience, and education, and be board certified and part of a professional association.

Participants and Players

All disasters happen at a community/local level. However, it is possible for local communities not to have access to all resources required to deal with an emergency situation. Therefore, emergency management relies on numerous stakeholders at different scales with the intention of community capacity building, which eventually will lead to building disaster-resistant and resilient communities. Some of the stakeholder agencies include the fire department, local law enforcement, health agencies, the Red Cross, the weather service (providing warning before an emergency), planning department, local/state/federal emergency management agencies, department of transportation, local schools/churches, community-based organizations, and private sector. The major actors are emergency managers: people with the ability to identify the main goals and possible solutions and to coordinate and collaborate with other stakeholders to achieve these goals. No matter the extent of aid an emergency manager can provide, emergency management actions cannot be effective without the participation of the local public, whose participation in the decision-making process and the different phases of emergency management is essential for the success of both emergency management and successful recovery of impacted communities. Thus, the second major players are citizens impacted by a disaster and they are at the grassroots level of emergency management.

Emergency Management Agencies, City and County

Local emergency management agencies—those organized at the city, town, county, or parish level and funded by and answerable to that local government—are typically the first agencies to respond to most emergencies, whether directly or through the coordination of local government resources. Many emergencies, including chemical spills, traffic accidents, structure collapses, fires, animal threats, and many weather emergencies, occur only on the local level and are best handled by local agencies that have both proximity and relevant familiarity. Other emergencies may require the attention of state or federal authorities, either for jurisdictional reasons (the federal government deals with terrorist attacks), the need for specialized competencies (the Centers for Disease Control and Prevention and other agencies have resources for dealing with infectious disease that go far beyond those of local agencies), or because the emergency transpires across multiple geographical jurisdictions. Wildfires, for instance, will frequently spread beyond the town in which they started and may transcend state lines as well as local boundaries. Major weather events like hurricanes, blizzards, and droughts are rarely confined to a small area. In these cases, multiagency cooperation is typical, with oversight and funding provided at the state and federal levels while local agencies do most of the footwork and contribute local expertise.

An emergency management agency oversees the response to an emergency and coordinates the efforts of the police department, fire department, emergency medical personnel, public works department, specialized rescue services (such as wilderness or mine rescue crews), hazmat teams, public utilities, social services, and other agencies with the resources and jurisdiction to respond. In addition, emergency management agencies are typically responsible for preparedness, mitigation, and public information, though these functions have a history of being downplayed in smaller jurisdictions because of budgetary priorities. The size, scope, and resources of a local emergency management agency vary greatly from jurisdiction to jurisdiction, and there is a historical relationship between emergency management and civil defense. New York City, for instance, has the Office of Emergency Management (OEM), a descendant of the Office of Civilian Defense established during World War II. The OEM's director reports directly to the mayor, and its headquarters is a four-story building housing offices for its staff, conference rooms, the emergency operations center, and briefing rooms for the media. The OEM's watch command, staffed round-the-clock every day of the year, monitors police and fire department activity and the 911 system, and it dispatches OEM responders as needed.

New York City, of course, has a population larger than most states. Although many other large cities, such as Boston, Seattle, and Chicago, have relatively large offices of emergency management, in smaller locales the office or its equivalent functions mainly as a liaison between the mayor and an emergency planning committee. Nashua, New Hampshire, the second-largest city in northern New England with a population of about 100,000, is a representative example, albeit one a bit more affluent than average.

Emergency Management in Nashua

In Nashua, the OEM coordinates city departments in the handling of disaster response and is the lead point of contact in nonpolice, nonfire emergencies. It is tasked with overseeing communications, transportation networks, infrastructure, and the flow of public goods and services during an emergency, as well as with the city's mitigation and preparedness. The OEM drafts the city's Comprehensive Emergency Management Plan, which details the actions and responsibilities of various agencies and departments in the event of an emergency, and runs the emergency operations center (EOC) during such emergencies. It is responsible for requesting assistance from other cities, or from the state or federal level, though in the latter case the request generally comes from the mayor.

The OEM develops the staff for the EOC and the internal procedures used to authorize emergency operations and is responsible for coordinating with the New Hampshire State Emergency Management Agency, as well as keeping the state up-to-date on damage assessments and other critical information. It is responsible for local alert systems for officials, procuring emergency communications equipment, coordinating public information programs, coordinating with medical personnel including hospital staff and doctors, establishing a shelter system that is compatible with the city's transportation resources, coordinating with volunteer groups like the Red Cross, and applying for matching funds from state and federal programs for emergency management funding. It also coordinates training programs for the public, for city officials, and for city departments.

The Nashua OEM operated the city's emergency operations center from October 29 to November 4, 2011, when the Snowtober nor'easter caused the third-largest power outage in the state's history, and the agency continued to oversee debris management through the subsequently mild winter until February 7, 2012. The response team consisted of the mayor's office, Nashua Police Department, Nashua Public Works, Nashua Public Health and Community Services, Nashua Fire Department, Nashua Information Technology, Nashua School District, Nashua Transit System, Nashua GIS, New Hampshire Red Cross, Southern New Hampshire Medical Center, St. Joseph Hospital, and Public Service of New Hampshire (the local electricity provider). Nashua North High School was used as a public shelter for a week, offering showers, hot meals, and access to electricity to those who had other places to stay, as well as overnight accommodations for those who did not. Functional needs support was offered to a greater extent than the city had been able to previously provide, and most of the residents who spent a week at the shelter made use of that support. The debris management program, restructured in the aftermath of the 2008 ice storm, which had left some parts of the city without power for weeks, was one of the largest in the city's history.

The example of Nashua and its actions during the Snowtober storm demonstrate the extent of an OEM's involvement in a jurisdiction too small to support an emergency services agency with a large full-time staff and dedicated resources, as would be found in Boston or New York. Key to the OEM's approach is organization and planning, which requires only manpower and appropriate core competencies. The resources of other city agencies, like the police and fire departments, and of the city's medical facilities can then be put to the most effective use.

Many city and county agencies have mutual aid agreements with one another, under which neighboring locations (or occasionally, separate agencies in the same jurisdiction) will lend resources and personnel to one another in response to an emergency. Calling for mutual aid is the decision of the incident commander. Mutual aid or reciprocal agreements are especially common with fire departments; the low frequency of serious fires makes maintaining a large firefighting staff and fleet an expensive proposition for a small town but also makes it likely that when a serious fire is occurring in one town, a neighboring town will have idle resources available. Such agreements therefore let towns spend less money on firefighting without seriously increasing their vulnerability to fire. Along the Canadian-U.S. border, there are international mutual aid agreements, involving both American and Canadian towns.

Even with mutual aid agreements, emergency management is a particular challenge in rural areas where the nearest town may be too far away for responders to arrive in time. Sparse populations contribute less human and financial capital, they exact a higher per-person cost for communications and other resources, and solutions to rural emergency management tend to focus on social capital—community organizations, the participation of local businesses whose interests are at stake, and volunteer labor. Volunteerism is generally higher in rural areas than urban ones; in some towns, local fire departments are staffed partly or entirely by volunteers, who are summoned from work or home to respond to fires.

California's Emergency Management

State law may dictate minimum standards of emergency management services at the local and county levels, as well as providing funding, resources, or structural support. The California Emergency Services Act, for instance, dictates the Standardized Emergency Management System (SEMS) for managing multiagency emergency response throughout the state of California. All state agencies are required to use SEMS, which incorporates the Incident Command System, interagency coordination, and the California Disaster and Civil Defense Master Mutual Aid Agreement, which dictates reciprocal agreements among jurisdictions. SEMS establishes an organizational framework for the response of emergency management agencies and for the integration of multiple agency responses. Local governments are required to use SEMS as a requirement of eligibility for disaster assistance and personnel funding from the state, and must maintain minimum SEMS training competencies, though they are not held to the same standards as state agencies. The prevalence of wildfires in California—which, if not properly dealt with by one jurisdiction, can quickly spread to others—was a strong factor in the passage of the Emergency Services Act, which was proposed after the East Bay Hills Fire of 1991.

The Incident Command System used under SEMS was developed by the Fire Fighting Resources of California Organized for Potential Emergencies (FIRESCOPE) program. Several key positions are defined and are filled by various local government officials as appropriate: the incident commander, who oversees the response to the disaster; the operations section chief, who oversees a specific section of operations; and the public information officer, who is the only designated media contact, charged with coordinating media relations and providing information about the ongoing disaster and the government's response. Ideally, there is a ratio of workers to supervisors of between 5:1 and 7:1.

SEMS also uses the Operational Area Satellite Information System (OASIS). The operational area consists of a California county and all its political subdivisions. Under SEMS, when a disaster occurs, the incident commander works with the planning section to draft an action plan identifying the agency's operational period and goals. The incident commander is a local government official, designated by the agency. SEMS is a scalable system. It's usable for five levels of emergency response: state, regional, operational area, local, and field levels. Emergencies that grow in severity or scope activate higher levels of response. At each level, SEMS identifies units responsible for operations, planning and intelligence, logistics (including personnel procurement, communications, transportation, and supplies), and finance/administration, each of which is further subdivided.

The operations unit, for instance, includes firefighters, law enforcement personnel, a medical unit, an environmental health unit, a unit providing care and shelter, and perhaps a separate animal services unit or other units needed in a specific emergency. For instance, in emergencies that call for an animal services unit, that unit is overseen by a branch director (or incident commander, if the unit is the sole operations unit) overseeing a planning group with teams assigned to resource control, emerging issues, and history (photo and video documentation); a logistics group with units devoted to communications, volunteers' coordination, and animal transport (including trailer crews, roadblock facilitators, a maps and logistics officer, and a support unit for the staging area); and an operations group, including medical aid (separate human and veterinary units), security, and facilities (including animal identification, housing, and sanitation/feed units).

Handling Evacuations

One of the tasks local agencies may have to take on is evacuation. Buildings and other small areas are evacuated during fires in order to mitigate exposure to risk and may also be evacuated because of damage from earthquakes or storms, chemical hazards, and human-made hazards. When police in 2012 investigated the home of alleged Aurora, Colorado, mass shooter James Holmes, they evacuated the surrounding area until the bombs he had set could be disarmed. Public places and transit may need to be evacuated in response to a bomb threat or suspected terrorist threat, a decision that may be made by state or federal authorities but is generally carried out by local agencies. Evacuations are also carried out in advance of hurricanes, wildfires, and tsunamis, and these evacuations are generally for a longer period, often requiring evacuees to remain away from the area for days, which may in turn require authorities to provide emergency shelters and provisions. The summer 2012 wildfires in Colorado required more than 35,000 residents to be evacuated by August; such evacuations require some amount of postevacuation monitoring of the affected area, as even residents who leave willingly may attempt to return before it is safe. Evacuations are rarely carried out in response to blizzards, but the need to provide food, shelter, and communications for a population displaced by structural damage or power outages encompasses a similar level of resource commitment as an evacuation.

When the affected area is large enough, evacuations may be issued by zip code rather than by neighborhood, which helps eliminate ambiguity and prevents the possibility of residents being left out of an evacuation because of a misunderstanding or geographic uncertainty. (Definitions of neighborhoods may vary widely and subjectively, and evacuation orders such as "all homes north of Central Street" may be unclear in locations where streets are not laid out in an orderly grid.) Communication among emergency workers is important during an evacuation, and ham radios are preferred because they are not dependent on cell phone towers, but it is even better to provide redundancy in communication options, so that if one option fails, another is available.

In some disasters, the evacuation process can be the most important part of hazard mitigation. In 2005, Hurricane Katrina's impact on the New Orleans area was exacerbated by the failure of the levees, but the human impact of the disaster was exacerbated by the handling of the evacuation. Authorities delayed in calling for a mandatory evacuation (in part because of the vagaries of predicting a storm's track, in part because of the expense required of such a declaration, which obligates government action), and by the time a mandatory evacuation order had been issued, it was given on short notice. Nearby motels in the safe zone were already occupied by people who had evacuated during or before the voluntary evacuation period, and these people were typically better off than those who remained, because of the expense of evacuating and leaving work. Therefore, those who did not leave until the mandatory evacuation period had farther to travel and more to pay in order to find safe lodging. In addition, not everyone had their own transportation with which to evacuate, and the transportation

RESCUE

A young boy is lifted to safety by first responders after his family lost everything in the flooding caused by Tropical Storm Erin in Kingfisher, Oklahoma, August 18, 2007. Because of their proximity and relevant familiarity, local first responders—city and county agencies—are the first to bring aid and comfort to victims following large-scale disasters, which would then require the additional response of federal agencies. Many other emergencies occur only on the local level and are best handled by local agencies.

provided by the government was insufficient, poorly organized, and poorly communicated.

Beyond the direct mishandling of the evacuation, however, human factors exacerbated emergency workers' task because of hurricane fatigue. New Orleans is in a part of the Gulf Coast that is subject to several hurricane warnings and watches a year. Most of the evacuations in recent memory had proven to be unnecessary. If there was clear information that Katrina would be a more serious storm than those of the previous decade, it wasn't effectively communicated—as evidenced by the surge in evacuation activity after the television appearance of the director of the National Hurricane Center, Max Mayfield, urging people to get to safety. Better oversight and integration of local, parish (county), and state agencies can in theory improve the handling of such situations. In the aftermath of Katrina, it was clear that so many things had gone wrong, in so many spheres, that blame was easily spread around.

Emergency agencies also need to have specific plans in place in order to evacuate schools, colleges, hospitals, and nursing homes. Often these institutions will develop their own plans, with hospitals maintaining a skeleton crew to care for patients who cannot be moved off-site. However, these plans should be integrated with the operational area's larger plan, and local authorities should remain informed about which hospitals (for instance) remain open for intake, which are operating but only have the resources to continue care for the patients they already have, and similar concerns.

Communicating information during an evacuation or any other emergency must be done with some thought to the effect the information will have. Broadcasting the locations of shelters, for instance, will result in those in need seeking the closest shelter—but if the shelters are not distributed evenly throughout the affected region, it will lead to overcrowding and insufficient resources in some shelters, while others will have empty beds. When possible, local agencies are better served by directing people to specific shelters in order to put resources to their most effective use.

Using Social Media

Local agencies are increasingly using Twitter and other social media to communicate everything from serious concerns to minor traffic snarls. The obvious drawback in using these media is that most residents are unlikely to be paying attention to the social media accounts of their local government agencies until they know something is wrong. Unlike an emergency alert on television, social media announcements do not interrupt the audience's other activities, but require that people opt for access to them, with the advantage that during power outages and other circumstances in which traditional media are difficult to access, social media may still be available via users' phones. Again, redundancy is key; Twitter should not be relied upon solely, but television and radio announcements, through public service announcements (PSAs) or the news media, can make the public aware of these social media resources.

A mobile or social media analogue to the emergency broadcast message has not yet caught on, but the Commercial Mobile Alert System (CMAS), developed by the Federal Emergency Management Agency's Integrated Public Alert and Warning System office, may fill that niche. The system was developed in response to the growing reliance on cell phones and abandonment of landline phones. Cell phones that are enabled to receive wireless emergency alerts (WEA) receive text messages sent by state, local, or federal emergency managers or the National Weather Service. Of the three types of alerts, cell phone users may choose not to receive Amber Alerts and disaster alerts, but they cannot opt out of presidential alerts. Instead of relying on area codes or exchanges to target a specific geographic area, as a landline-based system does, CMAS sends messages to those cell phones in range of the cellular towers in the relevant area, allowing for very specific geographic targeting. CMAS is not in widespread use, and local agencies must complete training courses in order to be certified in and authorized to use it. As of 2012, most Americans did not possess a WEA-enabled phone, but the frequent turnover rate of cell phones means that the majority of middle- and upper-class cell phone users are expected to have WEA-enabled phones by 2015.

New York City has gone the furthest in implementing the system, with the four major carriers (AT&T, Sprint, T-Mobile, and Verizon) engaged in initial tests; CMAS has not been used during an emergency since being rolled out. San Diego, California, has adopted the system as well, and other cities are expected to follow; the system is most useful in affluent areas, where much of the population owns and carries a cell phone. One of the difficulties the system has to overcome is the 90-character limit on its messages, about two-thirds of Twitter's 140 characters. A San Diego test message read "TEST: Toxic air quality near Mission Bay. Remain indoors. Turn off AC. Monitor local news," which conveyed a lot, but reservations remain about the character limit. Uniform resource locators (URLs) aren't used, despite the increasing popularity of smartphones, because data networks could be overloaded by too many people loading a Web page during a crisis. Similarly, too little information could lead to network overload as users call people looking for more information.

Social media can be effective not only in communicating during a crisis but also in community preparedness, risk mitigation, and safety advocacy. PSAs have long been used to communicate safety information about hazards such as downed power lines, digging where power lines might be located, or the dangers of falling bullets when holidays are celebrated with gunfire, as well as popular children's safety campaigns like the "Stop, Drop, and Roll" fire safety campaign. Social media can provide an extension of these campaigns and communication efforts. Furthermore, the use of social media fills the gap that is left as participation in community groups continues to decline.

Local agencies using social media should assign the task to someone already savvy with the technology and sensitive to the often bristly nature of the Internet. On Twitter, hashtags can be helpful to assist in users' searches for information, especially if the social media officer pays attention to online activity and can use a hashtag already in use by the public. Online videos can convey some kinds of information better than other forms of media, especially when instructing the public in emergency preparedness. Twitter-based "town hall meetings" have become increasingly popular as well and may attract participants who would eschew the trouble of an in-person town meeting.

Twitter and other social media are invaluable for "crowdsourcing," or assigning citizens to disseminate information during a crisis. Although this information should be received with a grain of salt, the public may be able to provide information about damage from an ongoing disaster more quickly than local agencies sending workers out to survey the scene. Agencies ignoring this information will look especially bad in the aftermath.

Emergency Management System

An emergency management system defines policies, procedures, and responsibilities for emergency management, including preparedness, mitigation, disaster response, and dealing with the aftermath of emergencies. A management system defines an organizational framework in which activity occurs—a framework in which, typically, interagency response is integrated, special procedures and responsibilities are defined, and methods for evaluating performance are established (based on the determination of goals and the preparation of after-incident reports based on those goals). Predetermining procedures and responsibilities streamlines the emergency response, as well as identifying in advance which resources will be needed in the event of various emergencies. Frequently, emergency management systems create temporary teams and hierarchies designed to deal with the emergency at hand, mobilize personnel from various agencies, and sometimes seek help from the private sector (especially medical personnel) and from volunteers (particularly via agencies like the Red Cross).

Historically, emergency management was a neglected aspect of the discipline of public administration, and it was left—explicitly or by default—to law enforcement agencies and fire departments, with contributions from public health organizations. Serious preparedness, and the maintenance of resources and personnel that would, ideally, be called upon infrequently, was an economic commitment too few communities were willing to make, and elected officials and voters alike regularly favored short-term gains over long-term thinking, an attitude that also exacerbated risk exposure in coastal, floodplain, and wildfire-prone areas. Emergency management remained focused principally on reacting to crises.

The creation of civil defense organizations, especially during World War II, did little to change this in the long term but did create some of the ancestral organizations of later emergency management organizations. Where emergency management organizations did exist, they were typically poorly funded and married to technology that soon became obsolete, as ongoing funding was rarely sufficient to replace, upgrade, or maintain the equipment that had been purchased with initial grants. This occasionally led to inefficient, even inept, handling of major disasters beyond the purview of the police department, such as public health crises or natural disasters. Problems arose when the agencies with the resources to act lacked the authority to act, and bodies with the authority to respond lacked the situational awareness and core competencies to capitalize on that authority. This was a perennial problem in some parts of the country where competent wildfire management demanded powers beyond what had been granted to the agencies set to the task, which is one reason why California led the way in advancing emergency management systems, long before concerns with terrorist attacks (national security prompted New York City and the federal government to follow suit).

In California, a standardized emergency management system (SEMS) was adopted after the

East Bay Hills Fire of 1991. SEMS establishes the emergency management procedures used by all state agencies in California, incorporating interagency coordination and reciprocal agreements among city and county jurisdictions. Local governments are required to be trained in SEMS and use it for emergency management if they wish to be eligible for disaster assistance and personnel funding. The system is used for five levels of emergency response: state, regional, operational area (county), local, and field levels.

SEMS calls for organizing human resources so there are no fewer than five and no more than seven workers under each supervisor. SEMS uses the Incident Command System (ICS), which was developed by the Fire Fighting Resources of California Organized for Potential Emergencies (FIRESCOPE). Under ICS, key positions are defined: the incident commander, overseeing the response to the emergency; the operation sections chief, who oversees a specific section of operations; and a public information officer, who is the designated media contact for the incident. The incident commander works with a planning section to construct an action plan that identifies the operational period and goals of the agency.

SEMS has five main components: FIRESCOPE's Incident Command System (ICS) and Multi-Agency Coordination System (MACS), the Master Mutual Aid agreement, the use of operational areas, and the Operational Area Satellite Information System (OASIS).

Incident Command System

FIRESCOPE developed the Incident Command System in the 1970s as an emergency management system for California's fire services, following a 1968 meeting of California fire chiefs. Its development came as a response to catastrophic fire damage, resulting in numerous deaths and widespread property damage, in California's urban fringe during large-scale wildfire suppression efforts. Authorities determined that the suppression efforts had been hampered not by insufficient resources but by management and communications problems.

ICS was later adopted by federal land management agencies as the standard emergency management system for all wildfire emergencies, and it became a popular model for emergency management of any sort. It was used in New York in response to the February 26, 1993, truck bombing of the World Trade Center, and in 2004 was included as a component of the Department of Homeland Security's National Incident Management System as a system to command, control, and coordinate emergency response by integrating personnel, policies, procedures, facilities, and equipment into a common organizational structure. ICS is now mandated for all emergency services that receive federal preparedness funding.

Like the rest of SEMS, ICS is scalable, providing a framework suitable for response on the local level, on the national level, or anywhere in between. In its general applications outside its origins in fire management, it is a first-on-scene incident management system, giving management authority to the first responder to an incident scene until that responder is relieved by a more qualified commander or the incident is resolved. ICS isn't a complete emergency management system—it deals with incident response and operations, not preparedness, risk mitigation, or aftermath.

Emergency management deficiencies often stem from unclear hierarchies, in which there are too many uncertainties about the chain of command and too little supervision, resulting in organizational blind spots and a general lack of accountability. A poorly defined or poorly informed planning process leads to wasted resources, and insufficient communication slows response time. When there are no predefined procedures to merge multiple agencies' efforts, cooperation becomes sloppy, determined by decisions made in haste and weakened by the cognitive biases of the on-scene responders making those decisions. The specialized jargon, procedures, and expectations of various agencies may conflict with one another and cause confusion. The strength of ICS is its emphasis on interagency cooperation to eliminate redundancy, keep agencies from tripping over each other, and reduce overhead and operating expenses; its command and control paradigm was originally based on that used by the U.S. Navy. ICS provides administrative and logistics support to emergency personnel and uses the resources from a scalable amount of inputs (agencies and other entities) in a unified effort with clearly defined roles, hierarchies, procedures, and offices of authority.

Under ICS, every individual has one and only one supervisor, and any supervisor will oversee three to seven individuals. (Under SMES, five is the minimum number.) The command structure is based on avoiding any possibility of conflicting orders or confusion over whom to report to, in order to hasten response time and minimize resource wastage. Command structure is assembled top-down on an as-needed basis; positions are not filled until they are needed. Positions can migrate to other individuals as the number of personnel involved in an incident increases, or as the situation changes—the first responder to the scene will be the initial incident commander, but command will later pass on to another responder if the incident continues. Similarly, common terminology is adopted and supersedes agency-specific terminology, though it can be difficult to ensure that this policy is implemented, especially in the heat of the moment when on-scene workers naturally revert to the jargon they're used to. Terminology for resources and positions in the hierarchy are straightforward.

ICS Management Objectives

Early in the management process, specific objectives are identified by the appropriate units, and units are then deployed to achieve those objectives, ideally in a specifically identified time frame. Strategies for achieving objectives are developed by the units best capable of doing so, not developed in a vacuum by workers unfamiliar with the terrain, in order to avoid the inefficiency of pursuing an unworkable or impractical strategy for the sake of orderliness. An incident action plan (IAP) is developed for the operational period, providing supervisors with actions to be accomplished in order to meet incident objectives. The IAP specifically identifies objectives, the individuals and units responsible for the specific actions that will achieve these objectives, communications procedures for the operational period, and the appropriate procedure to handle injuries. Hazardous materials incidents must managed with a written Incident Action Plan (IAP) prepared by the planning section; in other cases, the IAP may be written or oral.

Most incidents handled under the ICS are overseen by a single incident commander, though as noted that position may be passed from one individual to another. The incident commander is the final authority in decision making. In larger incidents, a unified command (UC), composed of two or more individuals, may govern; multiple-jurisdiction incidents are the most likely to use a unified command. The UC acts as a single entity and will usually appoint a single operations section chief who speaks on behalf of the UC as a whole in order to simplify the chain of command. Area commands are sometimes used in multiple-incident emergencies and oversee multiple incident commanders; they rarely include an operations component, and they focus on logistics and administration.

Other ICS staff positions include the public information officer, who is the designated media contact; the liaison officer, who liaises between agencies responding to the incident; the safety officer, who oversees efforts to preserve the safety of personnel; the operations section chief, who directs operations to meet incident objectives; the planning section chief, who collects the relevant information and oversees efforts to develop action plans; the logistics section chief, who oversees resources and support; and the finance and administration section chief, who tracks costs, requisitions, and other administrative data. In large incidents, there may also be a command-level information and intelligence officer. Under the Federal Emergency Management Agency (FEMA), it is common to have dual operations and logistics section chiefs, but this is considered a nonstandard application of ICS.

Among the standardized terminology established under ICS is the set of facility terminology. The incident command post (ICP) is the sole location from which the incident commander operates, but it may move during the course of the response. The staging area is the location where tactical resources await deployment, and there may be more than one. Camps provide services like food and shelter to staff, and bases are locations from which logistics and administrative functions are conducted. Helibases are secured locations where helicopters can land, refuel, and receive maintenance, whereas helispots are available only for takeoff and landing. A single location may be the ICP as well as a staging area, base, and/or camp. Large incidents may include a joint information center, where media representatives are engaged with; a joint operations center, usually predetermined; and a multiple-agency coordination center, the central command facility for overseeing strategic response to a large-scale disaster.

ICS resources are discussed in terms of "type" and "kind." "Type" is size, capacity, or other quantified information, whereas "kind" is the category of resource. For example, "100 kilowatts" is the type and "generator" the kind when speaking of a 100-kilowatt generator.

Today, ICS is used for terrorist attacks, medical emergencies, hazardous material emergencies, natural disasters and fires, vehicular and industrial accidents, hostage crises, and search and rescue operations. It is also used in nonemergency situations to manage agencies' involvement with planned events like parades, concerts, and fairs. It has been adopted by Canada, the United Kingdom, and Brazil, and New Zealand and Australia have adopted systems based on ICS. The United Nations has recommended it as the international standard for incident command and control systems.

Multiagency Coordination

Multiagency coordination is the coordination among agencies responding to an emergency, such as the police, fire department, and emergency medical technicians (EMTs) responding to a structure fire, the police agencies responding to a mass shooting, or the many agencies involved in responding to a deadly natural disaster. SEMS guidelines dictate the mechanisms of multiagency coordination at all five levels.

Multi-Agency Coordination Systems (MACS) are part of the national Incident Command System and provide the structure to prioritize incident responses, coordinate agency actions, and allocate resources to respond to large-scale emergencies. MACS are involved in providing each agency with the required situational awareness to make informed decisions, updating status reports across agency boundaries, establishing priorities among multiple incident commanders or area commands, anticipating resource requirements, resolving policy issues as needed, and coordinating strategy.

In an event in which multiple agencies are involved, a lead agency is designated for the day-to-day responsibility of administration. The lead agency typically takes the lead role in planning and developing the initial action plan, in cooperation with relevant local governments. County governments are the lead agency in operational area-level circumstances, though they have the power to designate another agency the lead agency following a joint resolution with member local governments.

The lead agency is sometimes a new or temporary agency created through a joint powers agreement (JPA) among local governments, an action authorized under California Government Code 6500 et seq. The JPA agency may also be a legal fiction representing the cooperation of multiple existing agencies, acting in concert. Under SEMS, a JPA agency may not be the lead agency at the operational area level if it is formed by more than one county. The JPA agency must be overseen by a policy-making body, as identified or established by the joint powers agreement, which consists of representatives from the signatory governments that are responsible for hiring staff, acquiring equipment and needed supplies, representing the JPA agency to other agencies, and applying for grants in the JPA agency's name. The joint powers agreement must be specific in the responsibilities and powers it assigns to the JPA agency, and it establishes specific staff positions.

Master Mutual Aid Agreement

Under California's Master Mutual Aid Agreement (MMAA), first signed in 1950, cities and counties voluntarily provide needed facilities and other resources to jurisdictions whose local resources are insufficient for a given emergency. When necessary, state agencies will also contribute. Agencies called upon by the MMAA are not limited to the fire and police departments but include medical resources and personnel, coroners' offices, search and rescue personnel, building officials, and public works staff.

Mutual aid sometimes includes providing staff members, especially support staff, to handle the increased workload in the nonoperations spheres during a response to an emergency. The governments of neighboring communities outside the area of the incident may provide some of their support staff to help fill needed staff positions or to populate the staff positions of a JPA agency.

Operational Area

Under SEMS, the operational area is the county and its political subdivisions. The county government is the lead agency in responding to emergencies at the operational area organizational level, and each California county is autonomous in determining its own organization and structure.

An operational area disaster council may be formed or designated to serve as an advisory body to the county government. In a situation where the lead agency handling the emergency is a JPA agency as discussed above, the operational area disaster council is typically the JPA policy-making agency. Such disaster councils are usually made up of elected county officials.

OASIS and NIMS

The Operational Area Satellite Information System (OASIS) is a satellite-based communications system designed to transmit data and status reports among California agencies participating in SEMS. There are 15 standardized forms used to transmit information from a satellite system in each operational area in California, each of which is linked to agencies at the local, state, and federal level.

The National Incident Management System (NIMS) is an emergency management system used by the U.S. government in conjunction with the National Response Framework to coordinate both incident management (through ICS) and preparedness among all levels of the public and private sectors. Whereas the National Response Framework, in effect since 2008, provides guiding principles for policy and coordination, and incorporates many of the principles of NIMS, NIMS provides a template much like SEMS. Adopted in 2003 by all federal agencies, NIMS is both standardized and scalable, providing operational structures applicable for any scale of incident and any number of relevant jurisdictions and agencies. Like SEMS, it is designed to be flexible and accommodate response to any kind of incident, including complex multi-incident emergencies.

ICS and MACS are the command and management component of NIMS, providing standardized terminology and organizational structure. The communications component emphasizes the use of plain language over jargon, as well as the need for interoperability, scalability, flexibility, and reliability. The preparedness component of NIMS calls for cooperation among all levels of government in order to achieve national preparedness. Preparedness is a constant, ongoing process, including planning, procurement, maintenance of resources, training exercises, and the constant evaluation of past performance and future scenarios as new information becomes available. Terrorism has especially been emphasized in the preparedness component, as a result of the role of the September 11, 2001, terrorist attacks in inspiring the creation of the Department of Homeland Security and the adoption of NIMS.

Agencies and entities involved with NIMS include law enforcement, fire departments, hazmat teams, emergency medical agencies, tow and recovery operators, highway departments, communication centers, and transportation management centers, as well as all federal departments and agencies.

National Integration Center

The Department of Homeland Security's National Integration Center (NIC) is responsible for the implementation of NIMS, including compliance specifications and ongoing administration. NIC promotes compatibility between the standards set by NIMS and those of other public- and private-sector groups, especially at the national level, and develops NIMS's national education and awareness program. It also oversees any review and revision of the NIMS system.

NIC is responsible for assessing the functionality and efficacy of NIMS's components and objectives, and it has jurisdiction over credentialing entities and personnel. It has established a database system for such credentials and works with standards development organizations to develop common national credentials.

NIC also oversees administrative matters such as establishing the naming and numbering conventions for NIMS-related publications and managing other elements of publishing such as distribution and product accessibility. It also assists agencies with NIMS training. NIC is a division of FEMA's National Preparedness Directorate.

Medical Surge Capacity Capability

The Medical Surge Capacity Capability Management System (MSCC) is the emergency management system used and developed by the Department of Health and Human Services' Public Health Emergency division, in the Office of the Assistant Secretary of Preparedness and Response. Whereas other emergency management systems are designed with a physical scene of incident in mind, MSCC is an adaptation of the Incident Command System and other NIMS elements to medical and public health crises in which either multiple incident scenes are extant, no one of which can be considered central, or in which there is no defined scene. This includes but is not limited to infectious disease outbreaks, contaminated goods or foodstuffs, chemical or biological weapons attacks, and exposure to hazardous materials.

The MSCC system was developed as part of the health care system's response to the 9/11 terrorist attacks, the 2001 anthrax attacks, and the 2005 devastation of Hurricane Katrina. It is designed as a medical emergency management system that establishes an organizational framework for meeting any major public health crisis. Unlike other applications of NIMS, there is also a strong focus on creating medical system resiliency such that health care organizations are able to recover quickly from disasters, mitigating the "secondary surge" of human costs when, as medical systems are overwhelmed by a disaster, patients in need of ongoing care suffer because of a medical attention shortage. There is a strong focus on information management, resolving interagency and policy conflicts, and medical asset support. As in other emergency response efforts, promptness is critical, and preparedness and risk mitigation shorten the time it takes to adequately respond to an incident.

Emergency Manager

The term *emergency manager* refers to the individual charged with creating the framework within which communities or organizations reduce vulnerability to hazards and cope with disasters. Although the position has traditionally been viewed as that of a technician specializing in disaster preparedness and response, the scope of the emergency manager has been evolving to encompass all aspects of community resilience, transforming the role of emergency manager to that of professional manager specializing in the development of emergency management programs.

Evolution

Although emergency managers are found in both the public and private sectors, the term originated with and is generally applied to public-sector employees. Although the function of government in reducing vulnerability and coping with disasters has been evolving over many years, the concept of a specific individual charged with discharging this function is of relatively recent origin and has its beginnings in the Cold War era. With the passage of the Civil Defense Act of 1950, the federal government began providing funding for local planners to develop plans for nuclear war. These planners were primarily retired military personnel who adapted military planning techniques to the various levels of government that employed them. Separate legislation (the Disaster Relief Act of 1950) provided for disaster response unrelated to civil defense and created a separate arm of the government to discharge these functions. However, these two functions were generally merged at the state and local levels. The result was a gradual shifting of the roles of the federally funded planners from nuclear war planners to all-hazards planners as the Cold War threat diminished.

Given its origins in Cold War nuclear planning, the role of the emergency manager has been closely associated with the development of the emergency operations plan and the position viewed as one of a technical specialist. The position tended to be plan-centric, with the major task of the emergency manager being to develop the emergency operations plan and prepare the jurisdiction for disaster response. However, with the adoption of the four-phase comprehensive emergency management model in 1978, there has been a growing recognition that emergency managers cannot limit their role strictly to response planning. Instead, studies have demonstrated that effective emergency managers share the same characteristics as effective managers in other fields. The increase in scope of duties necessitated by planning for mitigation and recovery in addition to preparedness, coupled with the advent of standards and program accreditation, has changed the role of the emergency manager from that of a planner to one of program manager.

This evolution from nuclear planner to all-hazards planner to program manager has been heavily influenced by a growing body of research on crisis and hazards, principally in the social sciences. Disaster research also has its origins in the Cold War: military planners were attempting to use natural disasters as a method of predicting the impacts of nuclear war on civilian populations. From this beginning, disaster research has grown to become an academic discipline in its own right and the theoretical basis for modern emergency management.

Current Role

The role of the emergency manager remains hard to define, as there is no standard job description. Until the adoption of the Principles of Emergency Management by several national emergency management organizations in 2007, there was no generally agreed-upon definition of emergency management. The actual role of an emergency manager seems to depend on two factors: (1) the size of the community and (2) the perception of competency of the emergency manager.

Where the community is relatively small, the emergency manager usually performs his or her functions as additional duties and is viewed principally as a technical expert in emergency response. The emphasis is on preparedness and response, and the majority of the effort is on developing the community's capacity to respond to crises.

Where the community is larger, the emergency manager tends to be a full-time employee, although not necessarily an emergency management professional. The role of the emergency manager tends to be broader in scope and moves toward community resiliency rather than just response. Mitigation of risk and planning for rapid recovery become part of this expanded scope.

However, even where the emergency manager is a full-time employee, the effectiveness of the position ultimately depends on the person holding the job. If the emergency manager sees his or her responsibility as encompassing all hazards and establishes his or her role in the organization as a program manager and peer, then he or she can make progress toward a goal of community resilience. However, if the emergency manager focuses solely on preparedness and response, his or her role will remain solely that of a technician with little influence on policy and strategy.

Toward Professionalism

The role of the emergency manager is in a state of flux. Although many emergency managers continue to view themselves solely as response planners, others see themselves on the verge of becoming a profession. Several factors are driving this move toward professionalism:

- The growing influence of professional associations such as the National Emergency Managers Association and the

International Association of Emergency Managers, which are seeking to establish standards and identify core competencies for emergency managers
- The development of core curricula and higher education degrees designed to prepare entry-level emergency managers
- The adoption and continued evolution of a professional certification by the International Association of Emergency Managers

Where the "traditional" emergency manager came to the position as a second career and saw the job as one limited to preparedness and response, the emergency manager of the future will most likely be someone who has chosen emergency management as a profession, has a degree in emergency management or a related field, is certified by a professional association, and sees his or her duty as one of increasing community or organizational resilience.

Emergency Medical Care

Emergency medical care is typically defined as medical services provided by pre-hospital care providers such as first responders, emergency medical technicians, and paramedics. Most people identify emergency medical services as the ambulance service; however, emergency medical care may also be provided by the fire department or law enforcement until an ambulance arrives.

Service Levels

Emergency medical care is provided at three levels. These include the basic level, advanced level, and critical care level. Basic emergency medical care is provided by emergency medical technicians (EMTs). This care may include assisting with emergency childbirth, splinting fractures, using bandages and dressings to stop bleeding, assisting with some medications, and securing patients involved in motor vehicle accidents. Basic emergency medical technicians may also use specialized tools, such as the Jaws of Life, to remove accident victims involved in accidents. Basic EMTs may also perform cardiopulmonary resuscitation (CPR) and the Heimlich maneuver to assisting choking victims.

Advanced emergency medical technicians (AEMT) and paramedics (formerly known as EMT-P, now just paramedic) provide advanced-level emergency medical care, including administering medications, intubation, and using electrocardiograms and interpretation of the information. Advanced EMTs are not licensed to perform the same level of advanced services as paramedics and are limited in their scope of practice. For instance, AEMTs can only assist with a limited amount of medications administered intravenously, such as glucose (similar to sugar water) and Lactated Ringer's (used to clot the blood). Comparably, paramedics are allowed to provide medications that AEMTs are not allowed to provide.

Paramedics may use a host of medications to assist the sick and injured, such as controlled substances for pain (e.g., morphine) or epinephrine for persons experiencing a heart attack or allergic reaction. Paramedics may insert breathing tubes into the airway to assist with breathing, use intravenous fluids, and use advanced electrocardiogram equipment that basic and advanced emergency medical technicians are not allowed to use. Paramedics typically perform their tasks under the authority of a physician medical director.

Emergency medical services (EMS) are required by state and federal laws to operate using various medical algorithms or preset directions. These algorithms allow EMS crews to provide patient care without a physician actually being on board the ambulance or next to the pre-hospital care provider. However, most EMS crews are required to contact a physician via radio or phone while providing care or soon after.

EMS agencies and private companies may employ basic EMTs, advanced EMTs, paramedics, or a combination of all three. Many communities provide tiered emergency medical services whereby all emergency calls are coded, or divided into the type of emergency. For instance, a person with a fractured arm may receive an ambulance staffed with basic EMTs, but a female giving birth may receive an ambulance staffed by advanced EMTs. However, a person experiencing a heart attack or life-threatening emergency will typically have an ambulance dispatched that is staffed only by paramedics. In tiered emergency medical service systems, the closest ambulance is dispatched first so that the patient receives some care until a paramedic ambulance can arrive. Ambulances staffed by basic or advanced EMTs may provide initial transportation and meet a paramedic ambulance en route to the hospital. This method of treatment and transportation ensures that the patient receives both immediate care and advanced care within a matter of minutes.

History

Emergency medical care can trace its roots all the way back to 1500 B.C.E., when local citizens were documented assisting travelers in need of medical attention. These local citizens would receive notification of injured travelers and respond by cleaning and bandaging their wounds, splinting fractures, and assisting them with temporary shelter until their wounds healed. Later, the Roman Empire used chariots and physicians to retrieve injured soldiers and provide care for them. However, French ruler Napoleon is credited with creating the first system of field care to include triage, treatment, and transportation all in one. Moreover, Napoleon's army also had standing protocols so that all physicians, nurses, and field providers offered the same emergency medical care no matter which part of the world they were in. Emergency medical care continued to develop as the United States entered the Civil War and both Union and Confederate armies created field battle aid stations where soldiers and sailors could be transported for emergency care. Other countries, such as the United Kingdom, Belgium, and Germany, continued to develop their own emergency medical services during this time as well. Private and municipal ambulance services begin to operate in major cities throughout the world in 1865 in cities such as Cincinnati, New York, and London.

The first documented introduction of cardiopulmonary resuscitation (CPR) can be traced to 1960. It was during this time that mobile intensive care units were introduced in Belfast, Ireland; Los Angeles, California; and Columbus, Ohio. Soon after, these same cities began to train emergency medical technicians and paramedics to provide care in the field under the direction of physicians. However, major conflicts such as the war in Vietnam led to new methods of providing field triage and care for soldiers that were quickly picked up by fire departments and ambulance services throughout the world.

The U.S. Department of Transportation's National Highway Traffic Safety Administration (DOT NHTSA) became responsible for all emergency medical services (EMS) training and oversight after the passage of the Highway Safety Act of 1966. This act gave the department authority over EMS because the majority of EMS calls received were secondary to motor vehicle collisions (MVCs) along the nation's highways and interstates. The act created a core training curriculum for emergency medical technicians, including response to these MVCs. The curriculum has been updated several times since 1966, with the most recent changes occurring in 1984 and again in the late 1990s. Aside from the National Highway Traffic Safety Administration, the National Association of Emergency Medical Technicians (NAEMT) has been instrumental in encouraging change within emergency medical services. Moreover, the NAEMT sponsors the National Registry of Emergency Medical Technicians (NREMT), which is the highest level of national EMT and paramedic certification available in the United States, Canada, and other developed nations.

Current Efforts

Major scientific advancements have continued to change the face of emergency medical care. These innovations include the use of advanced

Michelle Hollingsworth, a registered nurse, listens for breathing following simulated lifesaving measures during a hospital emergency response training (HERT) for mass casualty incidents course, Anniston, Alabama, January 21, 2011. HERT places emergency response providers in a realistic mass-casualty training scenario. Often, government grants assist public and private emergency medical care agencies with equipment updates and training, which has been especially critical since 9/11.

airway adjuncts, better medications, and highly advanced equipment such as the 12-lead electrocardiogram monitor and the pulse oximeter. In addition, ambulances are now equipped with advanced radio communication systems, computers, and other patient-care equipment. Emergency medical technicians and paramedics are now allowed to use advanced medications and protocols to provide better care for their patients. This includes new drugs to treat heart attacks (myocardial infarctions), drug overdoses, and strokes (cerebral vascular accidents). Paramedics are also allowed to treat patients for pain such as would occur secondary to a motor vehicle accident (MVA). In many states, EMTs and paramedics are allowed to staff hospital emergency departments, clinics, and outpatient surgery centers. Several larger states have recently moved from certification for EMTs and paramedics to licensure. This ensures that pre-hospital care providers receive a higher level of education than was previously required. Another aspect of emergency medical care is the emergency medical dispatcher (EMD). These professionals are trained to receive emergency calls, dispatch help, and provide emergency instructions to the person calling for help.

Future Efforts

Changes in emergency medical care include further integration of ambulance- and fire-based EMS into the public health community. These efforts include assisting with identification and modification of illnesses and management of those illnesses along with physicians, nurses, and other allied health professionals. Additional efforts include better integration with public safety agencies such as fire, police, emergency management, and homeland security, especially with regard to communications, research, and prevention. Conversely, public education, clinical care, physician medical direction, and improvement in training systems are being explored for the future. EMS agencies are also researching future improvements in patient care technology by beta testing new Web-based treatment between the ambulance and the physician at the hospital. This technology allows the physician to work with the paramedic to assess the patient via live video camera and then direct patient care before the ambulance arrives at the hospital. Similar systems are currently being explored for paramedics working on offshore drilling rigs and in remote villages.

One major concern for future efforts is the continued lack of funding for emergency medical care. Because many of the agencies providing emergency medical care are either volunteer service, fire-based response, or ambulances, or they are municipal-owned/third-service systems, a further reduction in budgets threatens to reduce these future efforts. Some communities have eliminated municipally owned emergency medical care agencies and instead have contracted with private companies to provide their emergency medical care and ambulance transportation needs. Although this move may save communities money in the short term, it may do little to support future efforts to provide first-class emergency medical care. Because these private emergency medical care companies are fee based, they may face similar budgetary constraints because they are not supported with public tax subsidies; they are paid only if they transport patients. These private companies are in business to make money and, like other businesses, they require payment for services rendered within a few days of the ambulance transport. This is a major concern in smaller communities that require an ambulance for emergencies but receive only a handful of emergency calls per month.

Private emergency medical care companies must find other ways to remain in business, including providing nonemergency transportation to and from long-term care facilities that often offer higher reimbursement for service than emergency medical calls provide. These concerns must be addressed by government agencies, communities, and nongovernmental groups before EMS can advance into the future. This may be difficult to do with private companies unless the company is well positioned to invest additional capital into these future advancements. Fortunately, local, state, and federal grants are often available to assist public and private emergency medical care agencies with updating both equipment and training for future advancements. This is especially the case since the terrorist attacks of 9/11, when so many emergency medical care agencies responded to provide assistance to the sick and injured.

Although many communities contract with private companies, they often remain involved in major operational decisions and medical oversight. Communities will often form emergency medical care committees and may involve local physicians, the fire chief, the mayor, or other community leaders. These committees ensure that the best emergency medical care remains available no matter if it is a public or private organization providing this care. Private companies are also providing fire service in many communities. These companies are often responsible for medical first response and may be dispatched to medical calls along with an ambulance. Because fire departments are often geographically located throughout communities, they are typically much closer to calls for help. A fire apparatus with personnel trained in emergency medical care will respond and provide care until an ambulance arrives. These crews are often staffed with emergency medical technicians, advanced emergency medical technicians, and paramedics. In some communities, all of the emergency medical care is provided by the local fire department, including all ambulance transportation.

Emergency Medicine

The first organized efforts to perform emergency medicine were undertaken during the French Revolution, thanks to the contributions of a French surgeon, Dominique Jean Larrey. In the wake of the Napoleonic armies, he conceived the idea of an ambulance, or, as it was called at that time, *voiture d'ambulance volante,* for the fast transport of wounded soldiers at the camp infirmary. He is therefore regarded as the father of emergency medicine.

Emergency medicine has historically experienced strong development in connection with large wars and with the application and development of military medicine. Over the past 20 years, emergency medicine has seen enormous growth, developing and requiring more skills over time. For example, an essential part of training and knowledge in this branch of medicine includes advanced trauma life support (ATLS), advanced life support (ALS), and advanced cardiac life support (ACLS). In addition, there has been a great development in technology, especially with the advent of the emergency room (ER), the first point of access to hospitals for patients in serious condition.

The notion of emergency medicine does not apply exclusively to the routine of everyday life (such as traffic accidents, domestic accidents, poisoning, burns, cardiac arrests, and other ailments), but also to situations that go far beyond the capacity for a system to respond, as in disasters, catastrophes, and crisis situations.

Responding to an emergency does not only involve rescuing the wounded or recovering the bodies (though such actions are certainly crucial in the early hours), but also includes addressing the many highly demanding organizational, social, psychological, economic, and moral problems that could affect both the population and health services.

Emergency Medicine Tools

Emergency medicine involves the combination of various disciplines aimed at achieving common goals, such as limiting the loss of life and restoring acceptable living conditions. The environment in which emergency medical operations are carried out requires a capacity for adaptation, which is typical of the field of medicine. Medical providers must be able to identify the priorities that characterize emergency medicine, take charge of a large number of victims, and consider each victim as an individual.

To achieve this and minimize improvisation, advance planning for an emergency should be based on a typically applied field of medical doctrine that maintains a hierarchy of tasks and an essential characteristic of the medical treatment of war. Every scientific discipline uses operational tools, and there are three tools that characterize emergency medicine: strategy, logistics, and tactics.

With the evolution of medicine and technology, an emergency is less defined as an uncontrolled event, for which a branch of medicine, studying global health interventions, has developed over time. Instead, emergency medicine can be considered a compilation of many types of medicine traditionally applied to a collective crisis or disaster.

Strategy, Logistics, and Tactics

Strategy is the art of designing emergency plans and consists of the following three key features:

- *Top management:* Emergency plans should be designed by experts with extensive experience.
- *Planning:* Designing a plan should consist of the analysis of a wide range of possible risks, and it should be noted that the implementation of a response must be based on the prediction of events related to the consequences thereof.
- *Training:* Operator training is a prerequisite.

Logistics is what allows the system to survive and function. It is literally defined as the art of providing and allowing a fair and rational deployment in the field of people, materials, and resources. It is necessary to establish some a priori criteria, such as the following:

- *Type of event:* For example, the collapse of a housing structure in an urban area will result in a type of response different from a train derailment, a blackout, or a pandemic.
- *Operating environment:* Environmental conditions strongly affect the system response, including such factors as the action taking place on uneven terrain, the presence of possible additional risks, difficulties in access to victims, climatic conditions, and the ability to channel resources effectively. All of these conditions must be considered binding management intervention.
- *Duration of the operations:* The autonomy of the rescuers and/or their rotation is an important variable for logistical purposes.

Tactics is the application of emergency plans by consequential operating procedures aimed at establishing the chain of rescue. This sequence is applicable in any event regardless of the type of crisis. The crisis management chain must meet the following requirements:

- The centrality of a single institution that receives the alarm, an assessment of the event size, and a prompt, coordinated response.
- Medicalization is at the core of emergency medicine. Even though the problems encountered in ordinary emergencies could become amplified, the most common error is to respond to an emergency by inordinately increasing the deployment of personnel and resources. Instead, the right approach is to establish priorities for evacuation to definitive care sites for victims.

Principles of Planning

Crisis situations are best managed under standard operating procedures (SOPs), and such procedures must be highlighted during the planning phase. Planning is a key step to having a good response strategy. It is a critical phase, and it is effective only when responders understand and can implement those plans.

It has been argued that it is necessary for planning to involve teamwork, in which all leaders and supervisors of the various structures or offices can work collaboratively to design a response plan.

Often, planning takes into account a broad range of scenarios, like a barricaded gunman, a hazardous material spill, a long-term blackout, a terrorist attack, or a pandemic disease. A plan should have an “all-hazard approach,” which could be applied to any critical incident regardless of its specific nature. It should meet the following criteria:

- The plan must be simple.
- All responders must understand the plan.
- All responders must practice the plan through training.
- The plan must be compliant with the National Institute Management System (NIMS).

Development of the plan begins with an assessment of vulnerability. The results of this assessment will show (1) how likely a situation is to occur, (2) what means are available to stop or prevent the situation, and (3) what is necessary for a given situation.

Developing the plan has other advantages. Unrecognized hazardous conditions that would aggravate a crisis situation may be discovered, and planners can work to avoid or totally eliminate them. The planning process may bring to light deficiencies, such as the lack of resources (equipment, trained personnel, supplies) or items that can be rectified before an emergency occurs. In addition, a plan should promote safety awareness and show the organization’s commitment to the safety of its workers.

Planners should take into account three areas of hazards: natural, technological, and human-made. Each of these presents specific risks that can be brought to a crisis situation such as an explosion, building collapse, major structural failure, spill of flammable liquids, terrorist activities, loss of electrical power, loss of water supply, and loss of communications.

Completing a comprehensive plan for handling crises is a major step toward preventing disasters. However, it is difficult to predict all of the problems that may happen unless the plan is tested.

Hospital Planning

Hospitals and health care facilities handle difficult situations every day. However, few of these situations usually send a hospital system into crisis, because there are more than enough resources to cope. Why, then, is it necessary to have specific planning for hospitals during a crisis situation? It is because a crisis situation might crash the entire apparatus of emergency room departments, aggravate the health status of patients, interrupt the flow of medical gases, result in the sudden interruption of electrical current, interrupt the communication systems, stop the flow of information, and significantly worsen the economic balance of a hospital.

Crisis situations are not all alike, and specific plans and procedures should be drawn up to cope with the various types of events that can lead to such situations.

This work must be carried out by a team composed not only of medical personnel but also of administrative personnel. The resource management procedures and diagnostic-therapeutic treatments must be provided after careful consideration of the following parameters: the expected type of event, type of risk, estimated number of injuries and diseases prevailing in each event, the location and extent of the affected area, infrastructure efficiency, and stockpile assessment of medicines and nonmedical supplies. During the planning period, as well as the later response phase, the crisis unit should be the executive core for providing both health care and administration.

Training

A plan cannot properly work without it first being tested. The training phase is perhaps the most important phase to verify if all the personnel (both medical and nonmedical) have fully understood the operating procedures of the plan, and if each component of the system fully understands its role.

Many universities are introducing specific degree programs concerning emergency medicine, specifically oriented to crisis and disaster management. The core content of these programs provides a list of all the topics, principles, and technical skills that students need to learn in order to perform certain jobs or duties. These skills and knowledge are gained by studying the definitions of a crisis or disaster and all its related features and the phases of a crisis response, and focusing on medical care and nonmedical care, including emergency medical care, with particular reference to trauma management. Other concerns during an emergency medical crisis include mental health, toxic-chemical injuries, mass burn care, pediatric casualties, and pharmaceutical distribution.

Beyond academic programs that provide the necessary base of knowledge, it is extremely important to offer continuous training for emergency medical personnel. Fundamental tools in this phase are tabletop exercises and drills.

In its official documents, the Federal Emergency Management Agency (FEMA) has outlined the guidelines for designing a tabletop exercise to simulate a crisis situation in an informal and stress-free environment. The participants are usually people on a decision-making level who gather around a table to discuss general problems and procedures in the context of a crisis or emergency scenario. The focus is on training and familiarization with roles, procedures, duties, and responsibilities.

Another interesting method is the Emergo Train System (ETS), which was designed at the Center for Research and Training in Disaster Medicine and Traumatology at the Kathmandu Medical College exchange program at Linkoping University in Sweden. In ETS, participants in real-scale simulations of emergency scenarios act exactly as they would in an actual crisis, with the only difference being that gestures on the field, operations, and interactions are represented on boards with the help of magnetic icons.

This greatly reduces the cost of the simulation, while still providing an overview of the general situation (especially during the moments of timeout and the final debriefing) as well as compressing the time intervals according to the time scale participants choose to use.

The simulation still has all the characteristics of a real-scale situation, including the emotional involvement of participants. The level of technical expertise required to interpret the various roles expected from the simulation can be modulated as a function of the specific objectives that are identified for the single scenario.

In contrast, training drills have a very different appearance, feature, and dimension, which, besides being designed based on specific scenarios, involve all staff and population. The drill's purpose is to test the response plan for specific situations. Topics increasingly relevant in these simulations are the possible massive influx of wounded, a possible blackout in a hospital, an uncontrolled pandemic disease, or a contamination by chemical, biological, radiological, nuclear, and enhanced conventional weapons (CBRNE) agents.

A crisis cannot be managed without a clear understanding of the operating procedures. In the early moments, two main factors have to be faced: uncontrolled panic and confusion. The purpose of the drills is to implement procedures to stabilize the scene, limit the acceleration of the growth of incident size, and ensure personnel's and civilians' safety; limit worsening of the already precarious health situations; ensure that all the procedures for scene management will be put into place through a rapid assessment; and subsequently establish the Incident Command System.

Response: ICS and HEICS

In the response phase, there are some goals that need to be reached after a crisis occurs. The first goal is to limit the growth of the incident and ensure the safety of both civilians and responders, and then stabilize the scene. Command must be assumed by an Incident Commander, and an Incident Command System (ICS) must be deployed.

ICS was created in 1980 and was originally developed in California under the FIRESCOPE program. ICS resulted from the obvious need for a new approach to the problem of managing rapidly moving wildfires in the early 1970s.

An ICS will provide for three types of operations: single-jurisdiction or single-agency involvement, single-jurisdiction or multiagency involvement, and multijurisdiction or multiagency involvement. The ICS must be able to adapt its structure to any emergency or incident and is a modular organization based upon the type and size of an incident.

Over time, specific ICSs have been developed. One of these is the hospital emegency incident command system (HEICS), which is designed to meet the needs of an internal response to the hospital (such as the medical care of mass gatherings, or sudden incidents inside the building, such as a blackout or system failures that could bring an interruption of medical gas erogation).

Based upon public safety's Incident Command System, HEICS has already proved valuable in helping hospitals serve the community during a crisis and resume normal operations as soon as possible. It has also assisted in the operation of a medical facility in a time of crisis.

In its August 1997 Healthcare Facilities Management Series, the American Society for Healthcare Engineering of the American Hospital Association stated that one of the best examples of emergency preparedness through checklists can be found in the HEICS.

The HEICS is primarily based on three factors: flexibility, minimal staffing (adding or removing positions), and cost-effectiveness (financial resources are saved by activating only those positions that are necessary).

In the response phase, emergency medical services (EMS) provide a significant contribution. EMS is a type of emergency service dedicated to providing out-of-hospital basic and acute medical care, transport to definitive care, and medical transport to patients with illnesses and injuries that prevent the patients from transporting themselves.

EMS personnel, whether they are emergency physicsian, paramedics, or emergency medical technicians, are also part of HEICS, and together with hospital personnel they help in incident and crisis management.

Triage and Medical Care Protocols

Beyond mere management, specific health protocols (triage and medical management protocols) often must be put in place for the recognition and management of critically ill patients. Triage is the process of determining the priority of patients' treatments based on the severity of their condition. The term comes from the French verb *trier*, meaning to separate or select. Originally created by a French doctor during World War I, it has been improved over the years and now is the most commonly used system to give priority of care to patients.

The most-used triage system in the United States is simple triage and rapid treatment (START). It was developed at Hoag Hospital in Newport Beach, California, for use by emergency services. It has been field-proven in mass casualty incidents such as train wrecks and bus accidents, though it was developed for use by firefighters after earthquakes.

There are four priority levels in which patients can be grouped: green, in which the casualty is classified noncritical and can wait for treatment; yellow, in which the casualty requires medical attention within six hours, or injuries are potentially life-threatening but can wait until the red casualties are stabilized and evacuated; red, in which the casualty requires immediate medical attention and will not survive if not seen soon; and black, which identifies all the casualties whose injuries are so severe that they have a minimal chance of survival.

Within the hospital system, the first stage on arrival at the emergency room is assessment by the hospital triage nurse, who will evaluate the patient's condition and designate his or her priority code so he or she can have access to the emergency room and obtain the appropriate treatment.

After triage procedures, emergency physicians, critical care nurses, and paramedics must follow specific protocols for medical care and major trauma management. These protocols are mainly based on a first rapid assessment and fast diagnosis, followed by stabilizing multiple injuries; mass burn care; rapid airway access; advanced cardiac life support; drug infusion; and medical care of biological, chemical, and radiation incidents. Besides these protocols that are specific for major trauma, medical teams usually have to perform certain tasks to avoid pandemic disease and its spread into the health care facility. This happened in 2003 in Toronto, when a young man presented at the emergency room with a "community-acquired pneumonia." He spent the night in the emergency room waiting for a bed. While he was waiting, he infected two patients and several staff members with severe acute respiratory syndrome (SARS). As result of this exposure, three people died and 31 became ill.

Emergency Operations Center

The emergency operations center (EOC) is a predesignated facility established by an agency or jurisdiction to coordinate the overall agency or jurisdictional response and support to an emergency. Although the physical facilities and operating structure may vary, all emergency operations centers share the common functions of situation assessment, strategy development, and resource allocation.

Core Capabilities

Although facility design and operational structure vary widely in emergency operations centers, there are several core capabilities that must be present for successful operations. The principal function of the emergency operations center is to develop a coordinated strategy for responding to an emergency. Successful accomplishment of this function requires that the emergency operations center staff be able to gather and assess situational information on which decision makers can base policies and strategies. Once the strategy is developed, the emergency operations center must have the capacity to implement that strategy through the allocation of resources, either as services or as tangible goods. These three critical functions place a premium on communications both internal and external to the emergency operations center.

Design

The design of an emergency operations center is determined by a number of factors. The ideal is a dedicated facility that provides sufficient operating space and environmental protection for the staff and has sufficient capabilities to support primary functions. For many jurisdictions, however, the emergency operations center is a dual-use facility that serves other daily functions such as meeting or office space and is configured at the time of activation. There are additional design concepts such as a virtual emergency operations center where participants are connected via teleconference, videoconference, and/or Internet connectivity, but these do not tend to be common. A number of agencies make use of mobile command vehicles that serve as emergency operations centers, although they are most commonly used as incident command posts at the scene of an emergency. The dedicated facility and multiuse facility remain the most common designs for emergency operations centers. No matter which design concept is used, there are several critical considerations in designing an emergency operations center.

The anticipated risks faced by the community determine the tasks that the emergency operations center must be prepared to perform. This needs assessment based on risk determines operating concepts, potential locations for the facility, staffing requirements, and so forth.

The location of the emergency operations center will have a bearing on the survivability of the facility and the speed with which it can be activated. A remote location requires additional staff travel time, which may be affected by damage to the road network. Locating the facility within a hazard zone means that it could potentially be unavailable when most needed.

Although there are core missions and functions for any emergency operations center, the operating structure used by the jurisdiction will determine which capabilities must be present, the number of staff, size of facility, and other factors.

Emergency operations centers are expected to have redundancy built in and be able function during any foreseeable emergency. Consequently, critical systems should operate in parallel so that the failure of one system does not compromise the facility's ability to perform its mission. The most critical systems usually involve communications and power, so emergency operations centers are normally equipped with alternative power sources and multiple communications systems.

Emergency operations centers need flexibility. Designs are based on best estimates of need at the time of construction. However, the advent of new technologies, the addition of new stakeholders, and changing operational requirements will require future changes to and reconfiguration of the facility. The emergency operations center design should contain sufficient flexibility to adapt to future changes.

Management

For the emergency operations center to function properly during an emergency. there is a considerable amount of preparation that must take place in terms of both preparing the physical facility and developing the policies and procedures to support operations and return the facility to a state of readiness. Note that these tasks are related to but not synonymous with the tactical activities performed by the staff. Where the tactical activities focus on response to the emergency, management

Case Study: Emergency Operations Center in the World Trade Center

In 2001, the city of New York had one of the most sophisticated emergency operations centers in the country. The facility was located on the 23rd floor of 7 World Trade Center (7WTC), one of the buildings in the World Trade Center complex. The facility had steel framing and Kevlar-reinforced walls designed to withstand 200 mph winds. It was located within walking distance of City Hall and key agency headquarters, such as the police and fire departments. 7WTC also housed the offices of key federal agencies such as the Central Intelligence Agency and the Secret Service and was considered one of the most secure buildings in New York. The facility housed computer-equipped workstations for up to 68 agencies, with an expansion capacity of another 40 stations. The workstations were arranged in a series of functional “pods” (e.g., health and medical or public safety), and each station was equipped with software unique to the user agency, allowing each access to its specialized functions. A briefing area for key executives overlooked the work area, providing a dramatic backdrop for media releases. The facility included a range of communications and video display systems.

On the morning of September 11, the Office of Emergency Management was forced to order the evacuation of the emergency operations center shortly after the second aircraft struck the Twin Towers. Because of the immediacy of the evacuation, only limited equipment and documentation were removed. 7WTC was severely damaged when the second tower collapsed later that afternoon, shortly after 4 P.M.

The emergency operations center moved to several temporary sites and was eventually relocated to the Police Academy, a site with limited space and communications. On the evening of September 13, the emergency operations center was relocated to a large warehouse space on the Hudson River.

Although the physical facility that housed the emergency operations center had been destroyed, along with all the documentation to support operations, the staff from the facility were intact and available to reconstitute the emergency operations center in the new location. Significantly, the staff chose to replicate the lost facility rather than to develop a new design on the fly. Consequently, the facility was designed using the pod concept and the executive briefing area that were familiar to the staff. The city arranged for rapid delivery of computers and network support and had an operational system within 36 hours. The emergency operations center continued to evolve over time, expanding to accommodate additional support agencies. Additional staff were provided through mutual aid and by Red Cross volunteers. For example, a detective from Nassau County, provided under a mutual aid agreement, was responsible for developing and implementing a logistics section. Federal agencies also opted to locate their operations at the new emergency operations center.

Coordinating the activities of so many participating agencies posed a significant problem. The emergency operations center staff once more made use of capabilities that had been put in place during the design of the original emergency operations center. The original center made use of an emergency management software program to provide situational awareness, coordinate activities, and manage resources. This software program was housed on the vendor’s server and was still available for use. It initially functioned as a virtual emergency operations center until the new site became operational and was eventually expanded to accommodate some 1,700 users representing over 150 agencies. Twelve wireless command post laptops were used to link the emergency operations center with field operations at Ground Zero and resource staging areas.

The reconstitution of the emergency operations center in New York following its destruction succeeded for a number of reasons. The first was the rapid evacuation of the staff, which not only saved many lives but also left the team intact to provide both continuity and institutional memory to the response operation. Second, New York was able to draw on a considerable amount of resources through its own large agencies, mutual aid resources, and private-sector companies and volunteers. This abundance of resources compensated for the lack of an alternate emergency operations center. Finally,

(Continued)

(Continued)

the decision to use the design of the destroyed facility for the initial layout of the facility meant that staff were working in an environment they understood and with which they were comfortable. The decision to house the emergency operations center at 7WTC, a facility in close proximity to where a terrorist bomb had exploded in 1993, would come under considerable criticism after September 11. However, the city had considered 55 other sites before making a final decision and felt that the secure nature of the building and the close proximity to key agencies outweighed the risk.

of the emergency operations is concerned with creating an operating environment in the facility that allows staff to conduct tactical activities with minimal stress and disruption.

Emergency operations center management falls into two broad categories: operations management and facility management. Operations management refers to the development of the procedures and documentation for use of the facility and supporting tactical activities. These include standard operating procedures for tasks such as activation and stand-down, administrative functions such as the process for ordering supplies, and checklists for use of equipment. Operations management also includes training and exercises to prepare staff to function within the emergency operations center.

The emergency operations center requires the same support as would any office building. The physical plant needs to be maintained, services such as security or janitorial provided, and supplies stocked. Activation may also require that routine services be increased or decreased and additional resources provided. This is the role of facility management and may be a more complex task than that of operations management as it involves multiple disciplines. In addition to the basic maintenance of the physical plant, it may also involve contracting, logistics, security, communications, information technology, catering, and so forth.

Operational Concepts

Response activity within the emergency operations center generally operates under one of two basic concepts. The general concept promulgated by the Department of Homeland Security is that of the emergency operations center as a multiagency coordination center. Under this concept, stakeholder representatives coordinate response activities and develop strategies that are implemented through normal agency chains of command. Senior agency officials provide oversight to this process as part of an interagency policy group. The emergency operations center does not direct field activity. This type of emergency operations center tends to be found at the federal and state levels and in large jurisdictions.

The second concept is that of the emergency operations center as command post. Under this concept, senior agency officials are present in the emergency operations center and directly in charge of the response. The emergency operations center in essence functions as an area command and directs the field response. This concept is generally employed by smaller jurisdictions that may lack the resources to staff both a command post and a separate emergency operations center.

Operational concept drives the operational structure, which, in turn, determines the configuration and layout of the emergency operations center. Operational structure generally tends to be functionally based, with staff organized either by branches and units under the incident command system or by emergency support functions where a primary agency coordinates the activity of multiple supporting agencies. In addition, most emergency operations centers place these functional groupings under the five basic functional categories specified by the incident command system: management, planning, operations, logistics, and finance/administration. These functional groupings determine the physical layout of the emergency operations center.

A common mistake is the assumption that the emergency operations center is for use only under the extreme conditions of a disaster. This attitude almost always results in the emergency operations center being activated too late in a crisis and the staff having little or no operational experience. Effective emergency operations centers are scalable and capable of providing support at multiple levels of crisis. For example, during an anticipated crisis or slow-onset event such as a flood, the emergency operations center may be activated with a small team solely for the purpose of gathering information on the potential event. Most emergency operations plans provide for a partial activation (i.e., limited staff) of the emergency operations center to support less-than-extreme events that do not rise to the level of disaster or to coordinate large civic events.

Leveraging the scalability of the emergency operations center allows for the following several benefits that increase organizational resilience:

- Provides staff experience with emergency operations center procedures and equipment
- Helps identify shortfalls in resources and capabilities
- Positions the organization to react quickly to an unexpected escalation of a crisis
- Imparts a positive public image of preparedness on the part of the emergency management organization

Emergency Public Information

During a period of emergency, information must be disseminated to the public, both by broadcast when possible and in response to specific inquiries. Emergency management personnel have discovered on many occasions the verbosity of members of the public during a crisis, and inquiries are limited not simply to people trying to get information they need (about hazards, emergency procedures, closures, the fate of loved ones) but include people offering help, donations, advice, complaints, and commentary. In many circumstances there is a tug of war to be adjudicated by whoever is managing the emergency: on one hand, the public is best served and best satisfied by information delivered in a timely fashion; on the other hand, the very nature of an emergency means that specifics of the situation could change rapidly, and information provided too quickly could be information that proves to be incorrect. Regardless of the reason for the error, the organization releasing the incorrect information will often be held accountable for it by the public. Information is ideally concise, so that it is easily understood, remembered, and repeated to others; it should also be clear and specific, containing exact directions for procedures the public should follow, if applicable, or precise cautions for how to avoid being impacted by the emergency.

Emergency Warning Systems

Information includes warning. Emergency warning systems exist in the United States for earthquakes, volcanoes, tsunamis, landslides, hurricanes, tornadoes, floods, avalanches, nuclear power plant disasters, hazardous materials storage site or transportation disasters, dam failures, nuclear attacks, and terrorist attacks, and the Emergency Broadcast System is available to communicate emergency warnings and other emergency information by radio and television. There is a great deal of decision making involved in emergency warnings: knowing whether an emerging situation merits a warning or not, whom to warn (the affected area is not always immediately clear, and warning too broad an area or the wrong area can clog the roadways during an attempted evacuation), and when to warn them. Likewise, the severity of the emergency dictates, generally, the manner of warning. Severe thunderstorm warnings will reach only those who happen to be watching television or listening to the radio at the time, unless they check the weather online or own a weather radio (a tone-alert radio that sounds an alert when a warning is issued). But the consequences of being unaware of a severe thunderstorm are mild enough to deem this acceptable. A nuclear power plant disaster, on the other hand, or a toxic waste spill may require the deployment of emergency personnel to deliver the warning street to street, door to door. Automated dialing of telephones to deliver a recorded message is also a possibility in many districts, though the diminished popularity of landlines as cell phones are adopted may mean this method reaches a smaller audience than it used to. Some emergencies are so local that broadcasting a warning is counterproductive: it is common practice for emergency personnel to notify neighbors of a home fire, or to ask bystanders to do so, in case anyone is home who could be placed in jeopardy if the fire spreads (or by smoke inhalation), or anyone elderly or disabled who needs assistance. Although the nature of the emergency in this case is severe, the number of people requiring the information is small enough and specific enough that use of a broader public outreach would not be effective. As with other emergency information, it is highly important that emergency warnings be clear, accurate, and specific, for the benefit both of those affected and those unaffected (and for the sake of making a clear delineation between the two, to minimize panic). Ambiguous and emotionally charged language should both be avoided.

In a Guaynabo, Puerto Rico, radio station, Justo Hernandez participates in a public service announcement (PSA) program that airs on several radio stations in Puerto Rico, September 15, 2011. PSAs are most often associated with radio and television.

Warning Decision Making and Delegation

Decisions about issuing warnings—and about all information dissemination approaches—should be informed by previous emergencies and the public response, in order to best prepare personnel for dealing with the public during the crisis. If the present emergency closely resembles a recent emergency in the same area or nearby, relevant differences between the two should be highlighted: it is important for the public to understand the need for a differently calibrated response to a well-organized strong hurricane after a damp disappointment of a tropical storm, but also important that they understand the difference between an airport closure while the bomb squad investigates an unidentified package and a known terrorist incident. The response to an emergency warning is a complicated process with both social and psychological factors; one person's response can alter, lead, or dampen another's, and people may respond differently depending on how they hear about it. One rule of thumb that seems to hold true is that the more specific a warning is, the more the audience will take it to heart: a warning issued to the Gulf Coast, to Louisiana, and to the French Quarter will be received with three different degrees of belief.

Of course, ultimately the most effective warning is the one delivered to a well-informed public.

Public outreach programs help prep the public to better receive emergency information by familiarizing them with emergency situations, whether endemic to the area (wildfires, blizzards, hurricanes) or plausible anywhere (terrorist attacks, hazardous material spills, prolonged power outages, heat waves, epidemics). A well-informed public can prevent emergency situations through their behavior in some cases, by adopting proper practices to avoid an influenza epidemic, for instance, and to reduce the risk of fires or the impact of droughts. This type of information encompasses not just knowledge but also skills: a public with better driving skills means an area less impacted by severe weather that affects road conditions.

Some organizations delegate emergency warning and emergency public information tasks to different groups or individuals, depending on the nature of their work, their relationship with the public, and the type of emergencies they handle. Preparing and disseminating information may, similarly, be two separate tasks. The public information officer (PIO) is a role found in many government organizations, serving a role similar to the public relations department in the private sector; very often PIOs are former journalists or journalism-school graduates, though increasingly, ideas from marketing and public relations are trickling into the profession at some organizations. This is less true with emergency services organizations, where community outreach and emergency preparedness/prevention may be a large part of the job but emergency public information remains the most important aspect of it. In some areas, police and fire departments and hospitals have separate public information officers; in others, emergency public information is consolidated in a single office.

Information can also include public service announcements (PSAs), which today are most associated with television and radio but which originated in newspapers during the Civil War and were an important part of the home front effort during World War II. Although PSAs are issued on a broad array of subjects to raise public awareness about various issues, many of them are concerned with emergency prevention or letting the public know what to do in a hypothetical emergency in order to increase the efficiency of response should such an emergency happen. Such PSAs were used to inform the public about the 911 emergency phone system as it was introduced in various parts of the country, for instance. PSAs may be nearly universal in their concern, such as those disseminating information about layman procedures for responding to health events like choking, heart attacks, or strokes, or disseminating broadly useful safety information about keeping children away from certain substances or avoiding downed power lines. They may also be local in their focus, familiarizing the viewer with local emergency services or warning about specific local issues, such as PSAs warning against shooting guns in the air to celebrate holidays in communities like New Orleans, where this is a cultural practice. PSAs may be made by government organizations, nonprofit groups, charitable organizations, or other groups; television broadcasters are required to devote a portion of their broadcast time to airing them.

Emergency Responders

Emergency responders (e.g., police, fire, health professions) play pivotal roles in managing crisis events such as acts of terrorism and disasters. They bring skills and competencies in key areas such as search and rescue, public order, and medical and mental health care developed in their routine work. However, differences between the contexts in which these competencies are normally used and those responders encounter when responding to crises means that training and development work is required to prepare emergency responders for the specific issues that arise in the alarm and deployment, response, and reintegration phases of crisis response.

Preparation

When responding to disasters and terrorist crises, emergency responders can find themselves facing atypical circumstances with little or no warning. This makes it important to train specifically for crises and to prepare for the implications of responding to them. Simulations and exercises that develop technical, psychological, and operational competencies are fundamental to building response capability and stress resilience in contexts that challenge assumptions and push boundaries. Simulations facilitate opportunities to develop technical and management skills, as well as response roles and responsibilities, and practice their application in realistic scenarios (e.g., infrastructure loss, multiagency operations, delegated responsibility, and information and decision management). They also afford opportunities to review plans, construct realistic performance expectations, rehearse translating plans into action, develop contingent capability to adapt to change, receive feedback on performance, and rehearse stress management strategies.

Given the difficulty of predicting what emergency responders could have to confront, training focuses less on events (e.g., earthquakes) per se and more on the event characteristics (e.g., physical danger, working in protective clothing, confronting biohazard agents, dealing with human remains, making complex and urgent decisions under conditions of uncertainty) that could occur across a range of events. For health care professionals, training would include performing clinical roles and triage under atypical circumstances and in ways that result in lower levels of patient care than would normally be expected. Training helps develop responders' capacity to render threatening experiences meaningful and facilitates effective performance by providing the competencies required to deal with atypical operating demands.

Emergency responders' experience of crisis events evolves over time as they progress through a series of stages, each with its own demands and characteristics. These stages are the alarm and deployment phase, the response phase, and the reintegration phase.

Alarm and Deployment

The alarm and deployment phase describes the period of comprehending and adjusting to a crisis event and mobilizing the emergency response. It involves, for example, accessing intelligence about what has occurred and making sense of often ambiguous information about the event.

In contrast to routine work, crisis events can introduce concerns about family safety. This is particularly so with terrorist acts where the potential for further attacks in unpredictable locations is present. Planning should advocate family preparedness and planning (e.g., support groups, access to antivirals, etc.) and, if possible, provide means for communication with families.

When deployed, responders' capabilities can be affected by transient factors such as health status (e.g., colds, flu), fatigue (e.g., deployed at the end of a shift), psychological fitness (e.g., occupational stress), and preexisting health issues. The personal and transient nature of these factors renders them difficult to manage. However, encouraging awareness of these limiting factors and their implications in training and advising of the importance of utilizing support resources can minimize their adverse effects on performance and well-being.

Initial problems accessing and comprehending information can result in responders being deployed before a full appreciation of the nature or implications of the event has been developed. This means that responders' understanding of events and its implications for how they utilize their plans, knowledge, and competencies evolves over the early period of their engagement. It is the responsibility of incident managers to clarify events and provide the structure required to move into the response phase.

Response

The effectiveness of response is influenced by organizational factors. For example, the more bureaucratic the organization, the more it persists in routine operational and decision procedures despite responding to different and urgent crisis demands. This results in inadequate consultation, poor communication, and excessive "red tape," making response to rapidly evolving issues more difficult. In contrast, organizations that develop crisis management procedures characterized by autonomous response systemsl flexible, consultative leadership; and practices that delegate responsibility and ensure that role and task assignments reflect incident demands facilitate an effective response. Deployment into crisis response roles differs from routine mobilization with regard to the fact that responders may find themselves working with both members of their own profession and representatives of other professions.

Team and Interagency Response

Crises present diverse problems and challenges. The need for these problems to be responded to simultaneously results in crisis response bringing together members of professions and agencies that rarely interact or collaborate normally. For example, the response to terrorist events could result in hazardous materials response teams; urban search and rescue teams; antiterrorism units; bomb squads; emergency management officials; private organizations responsible for transportation, communications, and construction; and medical and welfare agencies having to work together. The quality of response is a function of how well members of these agencies work together if required.

If members of different professions and agencies first come together during the crisis, the outcome is more likely to be conflict and a blurring of roles and responsibilities (e.g., regarding the lead agency, prioritizing problems). A capacity for cohesive response needs to be developed. Interagency team training can help deal with issues such as "turf protection," clarify interagency roles, and facilitate the development of a "super-ordinate group" whose membership reflects the collective role of all members in responding to complex, multifaceted crisis demands. This process culminates in the development of a team mental model that encompasses members' understanding of their respective contributions to the same plan and their shared understanding of each member's role in the response. This increases implicit information sharing during high workload periods, enhancing team capacity for adaptive response. This introduces a need to consider how information is accessed and used to make decisions in complex, evolving response environments.

Response Decision Management

In complex, multifaceted events, response effectiveness is a function of the capacity of responders to access, interpret, collate, and use nonroutine data and information from a variety of novel sources to interpret events and make response management decisions in effective and timely ways. The dynamic and complex nature of disasters and terrorist events introduces a need for several decision-making techniques. In complex, evolving settings, a level of creative decision making is required.

Where time permits, analytical decision making is the most effective technique. However, when time pressures are high, naturalistic decision making—where a responder recognizes the type of situation and, from previous experience, selects an appropriate course of action—is highly adaptive and is an essential competence. Interagency operations introduce a need for another decision-making technique.

Case Study: Emergency Responders in the United Kingdom

To respond to the growing need for search and rescue expertise in the aftermath of major crises and disasters, a United Kingdom organization was established to provide a volunteer resource in areas affected by large-scale natural disasters. Recruits were sought from the ranks of firefighters with several years experience in search and rescue work in domestic contexts. This approach to selection was informed by the assumption that the possession of appropriate search and rescue skills and experience would be sufficient preparedness for performing the same role in deployments of periods of two to three weeks in overseas disaster zones. However, early experiences led to the realization that this assumption was inappropriate. The disaster operating environment created unexpected operational and stress-related issues. Recognition of the significant implications that these issues had for team performance and well-being promoted a need for additional training to prepare responders for applying their search and rescue skills in crisis events.

Training needs analysis was conducted with responders who had experience of two deployments to different locations. This identified various issues that adversely affected performance. These included the level of destruction and infrastructure loss affecting performance, making normal management practices inappropriate, and reducing opportunities for effecting rescue; the level and duration of exposure to loss; injury and death sapping morale; conflict among team members and loss of interpersonal support; exhaustion from prolonged engagement in search and rescue work; conflict with search and rescue and aid groups; and media reporting. The last issue affected families back home and increased stress associated with concerns for the partner deployed to a disaster zone.

What was unexpected from the organizational perspective was that problems related less to people's technical skills and experience and more to how the environmental context affected both the performance and well-being of experienced responders. This prompted a need for training to develop the operational and team competencies required to function in these contexts.

The training needs analysis identified these issues as emanating from discrepancies between people's operational and performance expectations and the reality of disaster work. For example, the autocratic management style that proved effective when responding to domestic events was inappropriate for disaster settings. The scale of impacts meant it was difficult to adopt a command-and-control approach. Effective response called for participative planning and decision making to decide how and where to deploy the team. In contrast to normal circumstances, team members found themselves working alongside other search and rescue and aid teams. This created conflict and rivalries, confusion, and role and task ambiguity until some coordination of activities emerged on the ground. Responders also found themselves performing unexpected roles, such as media liaison about their successes and problems and finding themselves comforting relatives. Having to adapt to these issues affected performance and well-being. As a result, a training program was developed to prepare teams for such eventualities.

The training program was developed in collaboration between the external consultant brought in to conduct the training needs analysis and experienced team members. A decision was made that team members, rather than the consultant, would conduct the training. A significant benefit of using a train-the-trainer approach to delivering training was that trainers were able to reinforce the significance of issues (e.g., about emotional reactions). The training covered several areas. A combination of experienced disaster responders and video records was used to illustrate the operating context and the unique demands it made on personnel. The training addressed sources of stressors and advised of the normal emotional and psychological reactions that could be expected. It also sought to develop realistic and positive expectations about activities (e.g., recovering a dead body was not a failure for people who expect to rescue people), but something that gave families closure and opportunities to start the grieving process). Participative leadership and team management skills were taught. Buddy systems and peer support techniques were taught to allow members to provide social support in situ. Finally, outdoor survival training was conducted to develop physical and psychological resilience and contribute to team development.

Though not originally planned, an opportunity to evaluate the training arose when the team was deployed to a large earthquake in eastern Europe alongside a group of firefighters who had not received training in managing these contextual problems. This evaluation demonstrated that the training did enhance performance effectiveness. While not eliminating mental health problems, it reduced levels of stress experienced and hastened the rate of recovery, compared with those who had not been trained. Evaluation of the experience of both groups informed further training and organizational needs analyses and the development of the training and support programs.

The initial needs analysis identified family issues. These stemmed from concerns for a partner's safety when deployed, lack of contact, and increased stress and anxiety. Training and support programs were developed for family members. This involved advising family of how training enhanced the safety of team members. Family members were given opportunities to be involved during periods of deployment (e.g., administration, media liaison), and support groups were organized for family members during and after periods of deployment.

Distributed decision making recognizes the need for contributions from people who differ with respect to their profession, functions, roles, expertise, or level (e.g., operational versus tactical) of response management. Distributed decision making facilitates the capability of the multiagency team to utilize its collective expertise, even if contributing different perspectives, to manage the response. This is developed from exercises and simulations that contribute to developing a shared mental model. Responders' experience is also influenced by characteristics of the response environment.

Response Environment

The magnitude of the death and injury encountered, response constraints limiting the help available to casualties, and constant exposure to suffering illustrate the unique environmental characteristics responders can face. They may also face threats from, for example, disrupted sewer systems, working in unstable buildings, exposure to contaminated blood products, and threats (e.g., highly toxic chemical, biological, or radiation hazards) associated with biohazards or dirty bombs. The scale of destruction increases the risk of death in emergency response personnel. Death or serious injury to a colleague can amplify stress risk associated with an already hazardous environment.

Environmental factors such as heat, noise, or poor visibility affect performance and stress risk, as do the sights, sounds, and, especially, the smells encountered. The demands associated with environmental factors such as heat may be significant—and unexpected—as a result of the need to wear protective suits and breathing apparatus to protect from, for example, biohazard agents or toxic dust. This may be less problematic for groups such as firefighters who regularly use protective clothing and breathing apparatus but can be a significant stressor for those (e.g., police, EMT personnel) for whom this would represent a highly novel demand. The need for protective clothing contributes to stress risk directly (e.g., their use being necessitated by exposure to biohazards) and indirectly (e.g., increased heat stress and problems operating equipment).

The scale and nature of disasters and terrorist events means that emergency responders cannot perform at the level they would have expected (e.g., inability to rescue everybody as a result of limited resources, decisions resulting in some people not being helped). This can result in performance guilt. However, training that develops realistic outcome expectations and accommodates situational constraints on performance facilitates performance and well-being.

Stress risk is particularly pronounced when performing body recovery and identification duties.

Positive interpretation (e.g., interpreting body recovery duties in terms of their role in assisting families to begin the grieving process) can facilitate adaptation. Training and experience in handling body remains lessens stress in those exposed to this activity for prolonged periods. The final phase of emergency response commences with the cessation of the crisis role.

Reintegration: From Crisis to Routine

Reintegration describes the transition back into the "normal" roles and routines of work and family life. Key activities during this phase include managing any mental health consequences and reviewing performance. With regard to the former, it is worth noting that vulnerability is not restricted to those who had negative event experiences. Positive response experiences can manifest as stress reactions during reintegration if, for example, responders experience a conflict between a period of rewarding professional performance and readjusting to routine work and catching up with any backlog of work and dealing with reporting pressures.

Unique sources of stress during reintegration can arise from public and media scrutiny and sociolegal processes. For example, responders may have to contend with blame being directed at them (e.g., media accounts regarding event preventability, response effectiveness). Managing stress reactions from response and reintegration sources is important.

During reintegration, stress management centers on helping responders render atypical, threatening experiences meaningful. Resources such as coworker and peer support can be effective, as can communal coping. This is characterized by members' collective acceptance of responsibility for event-related problems and the existence of mechanisms by which they can cooperate to resolve problems. Acknowledging and building on effective collaboration during the crisis, and working together after the crisis, to develop understanding and enhance future preparedness helps mitigate stress and develop future resilience. Because stress issues can extend to include family members, organizations should develop family-friendly policies, family support groups, and family recovery plans to address this issue. The organizational context in which reintegration occurs has additional implications.

The Organizational Context

Event reviews and stress recovery are complicated if they occur in an organizational culture that discourages disclosure of event issues and emotions and focuses on attributing blame to responders for problems occurring during response. Positive reintegration experiences are more likely if managers actively promote and manage reintegration. This is particularly important with regard to issues arising from critical public and media scrutiny regarding event causation (e.g., beliefs that police were less vigilant than they should have been) and response management (e.g., beliefs that response could have been faster or involved inadequate resources).

Managers can assist adaptation by helping responders appreciate that they performed to the best of their ability. Managers can also facilitate positive resolution by assisting staff to identify the strengths that helped them deal with the crisis event and building on this to plan how future events can be dealt with more effectively. Such activities promote future response effectiveness and contribute to the development and maintenance of a resilient organizational climate and the development of training, development, and support practices that will enhance future response capability.

Emergency Support Functions

An emergency support function is a grouping of government and private-sector capabilities into an organizational structure to provide the resources that are most likely to be needed in responding to and recovering from a disaster. Each function has a designated coordinator for developing plans and one or more primary agencies designated for implementing those plans during a disaster. Originally developed as a mechanism of federal response, the emergency support function concept has been adopted by many state and local governments.

Concept and Evolution

The emergency support function concept was developed in response to the need to coordinate complex response activities by multiple federal agencies responding to earthquakes in California. As part of its earthquake planning responsibilities, Region IX of the Federal Emergency Management Agency (FEMA) conceived the idea of identifying the federal resources and services most likely to be needed following an earthquake and grouping them into functional categories. Each of these functional categories was assigned to a primary federal agency that had responsibility for developing plans to implement the function and for coordinating field activities related to the function during disasters. Other agencies that could contribute resources were identified as support agencies and agreed to provide planning assistance to the primary agency and to accept the primary agency's coordination role in implementation. This concept was incorporated into the National Plan for Federal Response to a Catastrophic Earthquake in 1985.

Following passage of the Stafford Act in 1988, the director of the Federal Emergency Management Agency was authorized to develop a plan to coordinate all federal response to disasters. The initial product of this planning effort was the Natural Disaster Response Plan in 1989, followed by the Federal Response Plan in April 1992. Both plans incorporated the emergency support function concept, solidifying its role as the principal federal response coordination mechanism.

The Federal Response Plan and the emergency support function concept were implemented almost immediately in Hurricane Andrew in Florida in August 1992 and in Hurricane Iniki in Hawaii in September 1992. Although the response to Hurricane Andrew was considered inadequate, the after-action report by the National Academy of Public Administration noted that the Federal Response Plan was an important step in coordinating federal disaster relief. The response to Hurricane Iniki went smoother as the federal staff adapted a number of mechanisms from the Incident Command System to coordinate activities among the emergency support functions.

With the formation of the Department of Homeland Security following the terrorist attacks in 2001, senior officials determined that the Federal Response Plan needed to be revised. The result was the National Response Plan issued in 2002. The new plan was not well received because of limited input from state and local governments during its development and was revised in 2006 to address problems identified during the response to Hurricane Katrina in 2005. The National Response Plan was quickly superseded by the National Response Framework, issued in 2008. Although there were changes made to the number and composition of the emergency support functions, each of these plans retained the emergency support function concept as the principal coordinating mechanism for federal response.

Federal Emergency Support Functions

The emergency support function concept has been a constant through all the various iterations of national coordination plans. However, the number and composition of the emergency support functions have changed. The Federal Response Plan identified 12 emergency support functions. This number was increased to 15 in the National Response Plan and the National Response Framework (see Table 1).

These changes have been necessitated by the changing demands for assistance, coordination issues identified in the field, and, in some cases, interagency politics. For example, the need for law enforcement aid to local governments following several response operations in the U.S. Virgin Islands led to the creation of ESF 13 Law Enforcement. Similarly, the title of ESF 6 changed from Mass Care to Mass Care, Emergency Assistance, Housing, and Human Services, and coordination responsibility was shifted from the American Red Cross to the Federal Emergency Management Agency. These changes reflected the increased levels of humanitarian assistance required in large events that go beyond simple congregate sheltering.

In addition to increasing the number of functions, successive federal plans also have made changes to previous functions and reassigned primary agencies. However, the single biggest change has been the dilution of the primary agency role. Where the Federal Response Plan identified a single primary agency for each emergency support function, the National Response Framework has as many as four primary agencies for each function. In addition, the National Response Framework also designates a coordinator position for each function, which may or may not be the primary agency, to develop plans prior to disaster activation.

Adoption by State and Local Jurisdictions

Although the emergency support function concept has been around for a number of years as the principal federal response coordination mechanism, few states and even fewer jurisdictions were inclined to revise their emergency operations plans

Table 1 Emergency support functions

Emergency support function	Federal response plan 1992	National response plan 2002	National response framework 2008
1	Transportation	Transportation	Transportation

13	–	Public safety and security	Public safety and security
14	–	Long-term community recovery and mitigation	Long-term community recovery
15	–	External affairs	External affairs

to incorporate the concept. Part of the reason for this was that there was no incentive from the federal government to do so. Further, *State and Local Guide 101: Guide for All-Hazard Emergency Operations Planning*, the definitive guide on emergency plan development, made no reference to the emergency support function concept.

This would change in 2008 with the publication of an interim edition of *Comprehensive Preparedness Guide 101: A Guide for All-Hazard Emergency Operations Planning for State, Territorial, Local, and Tribal Governments*. This document and the current version, *Developing and Maintaining Emergency Operations Plans,* published in 2010, offer three formats for emergency operations plans: a traditional format, the emergency support function format, and an agency-based format.

Several other factors have contributed to the interest of local government in moving to the emergency support function concept. The implementation of the national incident management system (NIMS) is a major attempt to standardize response efforts across the country. As part of this implementation, local governments have been encouraged to mirror the National Response Framework as closely as possible. Following the problems of Hurricane Katrina, the Department of Homeland Security has engaged in a major effort to review and revise state and local emergency operations plans. This initiative has included a series of nationwide plan reviews and funding for revising emergency operations plans. The combination of funding and federal emphasis has resulted in many jurisdictions revising their plans to incorporate the emergency support function concept.

Suitability for State and Local Governments

Use of the emergency support function concept by state and local governments offers some advantages but also raises some concerns. Despite its relative success at the federal level, there are no empirical studies demonstrating the effectiveness of the concept at any level of government. The emergency support function concept evolved to meet a specific need: the integration of multiple federal agencies into a single disaster response framework. Although there would seem to be similar needs at state and local levels, there are qualitative differences that may make the concept difficult to apply in smaller jurisdictions.

Even at the federal level, agency resources are such that emergency support functions are seldom staffed by multiple agencies. Consequently, there is a tendency to identify the function with an agency. That is, the representative of a primary agency for an emergency support function may also be the point of contact as a supporting agency for other emergency support functions.

Several of the functions identified may not be necessary for a smaller jurisdiction. For example, the functions of ESF 7 Resources Support may already be integrated into the response framework established by the jurisdiction. It has also been suggested that some of the emergency support functions identified in the National Response Framework have pre-disaster planning functions but only limited disaster response roles (e.g., ESF 5 Emergency Management). This raises the questions of standardization and whether jurisdictions are free to create their own emergency support functions or change titles and numbering.

Another potential problem with the emergency support function concept is that tasks requiring multiagency response can become diffused across multiple annexes. This is can be addressed by the development of a support annex that describes the overall concept for the task, with the emergency support function annexes describing the specific responsibilities of each function. However, *Comprehensive Preparedness Guide 101* states that support annexes identify a coordinating agency and assisting and cooperating agencies in addition to describing the mechanism for coordination and execution of common strategies. It does not address the interface between the support annex and the emergency support function annexes. Synchronizing these multiple annexes creates a significant planning burden for a small jurisdiction.

The emergency support function concept does not align with the incident command system mandated by the national incident management system. The National Response Framework places the emergency support functions under the Operations Section. This is appropriate where the role of the functions is to provide external support to affected jurisdictions. However, the agencies at the local level have this external support role

Case Study: Emergency Support Functions for the 1994 Northridge Earthquake

At 4:31 A.M. on January 17, 1994, Los Angeles, California, was struck by a magnitude 6.7 earthquake that killed 57 people, injured 8,700, and caused over $20 billion in damage. Within the hour, Federal Emergency Management Agency (FEMA) Region IX activated its regional operations center. The regional operations center staff included a representative from each emergency support function primary agency. These representatives were largely drawn from the Regional Interagency Steering Committee, a planning group that met regularly to develop implementing strategies for the Federal Response Plan. The members were well known to each other and had worked together on previous disasters in Region IX.

These representatives were tasked with gathering as much information as possible about the impact of the earthquake and with determining and alerting potential resources. Some representatives were given immediate mission assignments or activated resources under pre-existing agreements. For example, ESF 9 Urban Search and Rescue began assembling and deploying an overhead management team and activated the standby search and rescue teams for immediate deployment.

As the team at the regional operations center worked on assessments, FEMA assembled and deployed an advance team to southern California that included primary agency representatives from the emergency support functions. The advance team established a disaster field office in Pasadena and assumed control of the response from the regional operations center by the day following the earthquake.

Within the field office, the emergency support functions established work areas in the Operations Section. Although the Federal Response Plan identified a primary agency and multiple support agencies, most emergency support functions were staffed by the primary agency. In some cases, this was a single individual, and the emergency support functions were sometimes identified by the staffing agency rather than by number. For example, ESF 6 Mass Care was usually referred to as "the Red Cross." In addition, some primary agencies also provided resources to other emergency support functions. For example, the U.S. Forest Service was the primary agency for ESF 4 Firefighting and also provided staff to ESF 5 Information and Planning.

Previous experience in Hurricane Iniki in Hawaii in 1992 had led to the establishment of two important mechanisms for coordinating the activities of the emergency support functions. The first was a daily coordination meeting facilitated by ESF 5 Information and Planning. The coordination meeting focused on identifying problem areas and assigning lead and supporting agencies to each problem area. Primary agency representatives received a short update on the current situation, supplemented by a daily activity report and briefing package, and then were asked to briefly describe problems areas with which they needed assistance. The Operations Chief then assigned support resources and progress was tracked at subsequent meetings.

The second critical mechanism was a documented mission assignment process. Federal funding for disaster activities was funneled and tracked through FEMA. Agencies could not seek reimbursement for any operational expenses without a specific request by FEMA. Although the mission assignments were generally given to the primary agency, it was sometimes necessary to directly mission assign a supporting agency, making the mission assignment process cumbersome and hard to track. Delays in providing mission assignments had created problems in previous disasters, and the Operations Branch had developed a system to avoid this in the Northridge response.

A significant advantage for the emergency support functions was the large amount of resources available to the state of California's Office of Emergency Services. The state attempted to merge its field operating structure with that of the federal team as much as possible. For example, the state plans unit was collocated with ESF 5 Information and Planning, and information was freely exchanged between the two units. The state was also able to assign agency representatives directly to the emergency support functions, thereby creating multi-jurisdictional teams.

Resource requests from the affected area were provided first to the Operations Chief, who determined the appropriate emergency support function to provide the needed resources. Within the emergency support function, the state and federal representatives determined which federal or state resources were most readily available, requested a mission assignment tasking, and then implemented the agreed-upon course of action.

The use of the emergency support function concept in the response to the Northridge earthquake proved highly effective for a variety of reasons. The previous working relationships established among the primary agencies meant that problems or gray areas within the Federal Response Plan could quickly be addressed. The same was true with the state agencies, as many had preexisting relationships with their federal counterparts. The use of ESF 5 Information and Planning as a plans unit allowed the consolidation of information from the emergency support functions, making it accessible to any agency. The use of facilitated planning meetings and mission assignment tracking, along with a close working relationship between the emergency support functions and their state counterparts, avoided duplication of effort and ensured that relief was provided as quickly and efficiently as possible.

and an additional internal support role under the Incident Command System. For example, agencies assigned to ESF 7 Resources Support at the federal level deploy resources to the disaster area. At the local level, these agencies will most likely be assigned to the Logistics Unit. The emergency support function concept does offer considerable value as a planning tool, however. Identifying critical response functions, identifying agencies associated with those functions, and designating a primary agency with responsibility for planning and implementation of tasks to accomplish the functions in effect creates a task force that can be highly effective. Of particular value is the ability of the concept to integrate not only public-sector agencies but the private sector as well.

It is this use as a planning mechanism that gives the emergency support function concept its true value. During response operations, the emergency support functions serve essentially the same purpose as previous coordination mechanisms, although their efficiency is greatly improved by preoperations planning. However, the existence of preidentified teams with clearly defined responsibilities and leadership allows for the expansion of the emergency support concept beyond just emergency response. The emergency support functions offer pools of expertise that can be used to enhance mitigation and recovery planning and can provide support to lower-level emergencies that do not rise to the level of disasters. Consequently, judicious use of the emergency support concept can be used to bolster overall organizational resilience.

Environment Programme, UN (UNEP)

The United Nations Environment Programme (UNEP) is the environmental extension of the United Nations (UN). The UNEP fosters and advances partnerships between diverse actors, including other international organizations, national governments, nongovernmental organizations (NGOs), and the private and public sectors.

The UNEP advocates the protection of environmental resources in tandem with the promotion of development initiatives that improve the quality and standard of living for member countries.

Formation and Mission

The UNEP, established in December of 1972 through the UN General Assembly Resolution 2997 (27), was born out of the UN Conference on the Human Environment in Stockholm, Sweden, held in June of that same year.

The UNEP's mission statement is "To provide leadership and encourage partnership in caring for the environment by inspiring, informing, and enabling nations and peoples to improve their quality of life without compromising that of future generations."

Structure and Roles

To meet its mission statement, the UN employs a secretariat of approximately 900 individuals. These staff members function as an executive department, applying the budgeted priorities of the UNEP, such as policy implementation.

The Governing Council (GC) of the UNEP, comprising 58 representatives from UN member states, is tasked with the diplomatic aspects of the program, such as facilitating collaboration between and within the UN and other agencies. The GC also authors the primary environmental policies of the UNEP, which are executed by the secretariat.

Representatives are elected by the UN General Assembly (GA) for three-year terms and are delegated based on six geographical regions. The GA also elects the UNEP executive director to a four-year term. The UNEP executive director is traditionally nominated by the UN Secretary-General.

The UNEP is headquartered in Nairobi, Kenya, and supported by six regional offices located in Africa, Asia and the Pacific, Europe, Latin America and the Caribbean, North America, and west Asia. Each area is overseen by a regional director, who works in tandem with the nine members of the UNEP senior management team, overseen by the executive and deputy directors.

The UNEP is tasked with a series of important roles, which include (1) monitoring and evaluating known and potential environmental threats; (2) anticipating and preparing for future environmental crises; (3) conducting scientific research; (4) disseminating this research through reports, books, and popular media; (5) organizing and hosting regional and international conventions on relevant environmental issues; (6) raising global awareness on crucial environmental issues; (7) promoting joint environment-development projects; (8) developing and implementing regional and international environmental policies; (9) assisting member states in achieving environmental goals and meeting environmental mandates; and (10) coordinating environmental efforts with other arms of the UN.

These roles are administered through the following environmental priorities of the UNEP: climate change, resource efficiency, disasters and conflicts, environmental governance, harmful substances and hazardous waste, and ecosystem management.

Accomplishments

One of the primary challenges facing the UNEP concerns its institutional capacities, which are limited in scope by insufficient funding. Another difficulty includes traversing the diversity of political landscapes that constitute the body of its constituency. In spite of these challenges, several major global environmental accomplishments have been brought to fruition.

One of the UNEP's most widely recognized global achievements is the Montreal Protocol, an international environmental treaty established in 1987 to combat the destruction of Earth's ozone layer. The UNEP is also credited with the establishment of the Intergovernmental Panel on Climate Change (IPCC) in 1988, and with the introduction and dissemination of the "sustainable development" concept through *Our Common Future*—a special report by the Brundtland Commission.

The UNEP is lauded for organizing the UN Conference on Environment and Development in 1992. Also known as the Earth Summit, the conference is recognized for a concerted effort to conflate economic development with environmental protection, through a report titled *Agenda 21*. More recently, the UNEP has been instrumental in advancing the Kyoto Protocol, first introduced in 1997. The document is an environmental treaty, international in scope, with the goal of stabilizing greenhouse gases that are contributing to global climatic changes. These accomplishments demonstrate the UNEP's ability to coalesce different actors, agencies, and governments around environmental issues of a global scale.

Criticisms

Many of the critiques lodged against the UNEP stem from the program's ambitious mission statement, its large constituency, and the scale of the issues it addresses. In particular, the UNEP is often accused of being an ineffective and poorly organized juggernaut. Its lack of a long-term plan, coupled with largely qualitative goals, renders meaningful organizational evaluations difficult or impossible. Furthermore, it is not an independent agency with autonomy in decision making but instead reports to the UN General Assembly.

Many criticisms are linked to issues of UNEP funding, which is not guaranteed but supplied by entirely voluntary contributions from its member nations. This issue of disproportionate financing has resulted in an unrepresentative distribution of lobbying power and influence by some nations within the program, which also reduces program autonomy.

Dissatisfaction with the organization, led primarily by accusations of ineffectuality, led to a situation whereby 46 countries supported and signed a document titled *The Paris Call for Action*. This document advocated the dissolution of the UNEP and its replacement with a new organization called the United Nations Environmental Organization (UNEO). Signing countries believed the UNEO, if structured in a fashion similar to the World Health Organization (WHO), would be more effective and less constrained than the UNEP as currently structured.

Environmental Contamination

Since the industrial age, a major threat to the health of human beings and wildlife has been threaded by environmental contaminants. Environmental contaminants found in water, air, or soil are either human-made or natural. The risk associated with exposure to chemicals cannot be quantified or assessed. The risk of chemical exposure resulting in some form of injury may have by far better results in stored historical data, whereas assessing the risk of chemical exposure with no immediate form of injury has less observed data. Risk assessment examines hazard identification, dose-response assessment, exposure assessment, and risk characterization to characterize the nature and magnitude of health risks to humans, animals, and crops from chemical toxicants and contaminants. In hazard identification, the nature

Inside the Caribbean Petroleum Corporation (CAPECO) explosion perimeter in Cataño, Puerto Rico, a firefighter adjusts respiratory gear, October 24, 2009. The explosion and fire at CAPECO produced an environmental contamination crisis with a toxic fire, which took firefighters over two days to extinguish. There were fuel leakages into neighboring waterways, soil contamination, and hazards to public health. An investigation revealed CAPECO had been cited multiple times for serious environmental violations.

of toxicity of chemicals to human and animals is determined in terms of its quantity. For instance, exposure to nuclear power causes thyroid cancer. The relationship between the amount of exposure and the effect of a toxin is measured by dose-response assessment in risk management. Exposure assessment measures the amount and length of exposure to chemicals from consuming water, eating food, or inhaling polluted air. Any adverse health effects and their potential incidence are estimated by risk characterization, which measures the likelihood of a population's exposure to some given type of chemical.

The environmental risk assessments of contaminants fall into two areas of human health and ecology to find how much a chemical is present in an environment or how much a person or ecological receptor is in contact with or at risk of exposure to the contaminated environment and, more important, how toxic the chemical is. Chemicals can be less toxic if the dose is low enough.

Who Evaluates the Risks?

If risk assessments provide information on the potential risk in health and the environment, risk management is the action taken based on considerations made under risk assessment, scientific factors like toxicology and statistics, economic factors to inform managers of the cost of toxicant risk present in the workplace and benefits of reducing it, laws and legal decisions, social factors like community values, land use and zoning, and public values that reflect the society as a whole and their attitudes on risk management and assessment.

Various federal agencies such as the U.S. Environmental Protection Agency (EPA) are responsible for assessing and managing risks associated with stressors. The EPA's Office of Air and Radiation (OAR) is responsible for air pollution stressors; the Office of Solid Waste and Emergency Response for hazardous substance, pollutants, and waste; the Office of Pesticide Programs (OPP) for pesticides; radiation programs responsible for radiation including radon; the Office of Pollution Prevention and Toxic (OPPT) for human exposure, environmental exposure, and toxic substances; the U.S. Consumer Product Safety Commission (CPSC) for pesticides; and the Food and Drug Administration (FDA) for pharmaceuticals and vaccines.

Human-Made Chemicals

Most human-made chemicals are colorless, tasteless, and odorless and are hardly detectable. Synthetic organic chemicals (SOCs) such as pesticides, herbicides, and insecticides, and volatile organic chemicals like solvents and gasoline, are human-made chemicals found in the environment. Because of improper storage, use, or disposal of chemicals, the safety of soil and especially drinking water can be of concern. Cleaning up water after contamination is costly and more difficult than preventing water from contamination in the first place. Human-made, industrial, and manufacturing chemicals, pesticides, and ammunition wastes along with grain fumigants, have been detected in groundwater systems and in soil. Environmental contaminants, many of which are human-made chemicals, are found in nature and act as hormones or antihormones and endocrine-disrupting contaminants (EDCs). As a result of the introduction of EDCs by humans and their activities, modified reproductive anatomy, altered fertility, and impaired hormone secretion have been seen in wildlife. Studies at the Marine Environmental Research Institute (MERI) show that human-made toxic chemicals and compounds seen in cars, homes, and schools have been found in Maine harbor seals' bodies. These toxic compounds found in seals' bodies are among the highest in the world in terms of toxicity. Toxic compounds such as dioxins, DDTs (dichlorodiphenyltrichloroethane), mercury, pesticides, and polychlorinated biphenyls, along with organic pollutants, have been found in the seals' bodies; many of these toxicants are persistent in terms of entering the food chain and can be recycled for decades. We are consuming the same kinds of fish that seals eat, such as mackerel, flounder, and hake.

Drinking Water Contaminants

Contamination of water has been a concern to the public for years. Water contaminants can be characterized as microorganisms, disinfectants, disinfection by-products, inorganic chemicals, organic chemicals, and radionuclides. In the United States, concern has been increasing over the outbreak of some of these microorganisms such as cryptosporidiosis, giardiasis, coliform bacteria, and hepatitis A. Coliform is a bacterium that lives in soil or vegetation and mostly enters the water streams by direct disposal of waste into the streams. A human's immune system determines whether the person will get sick or not. Many people become immune to these types of bacteria even if they are found in the drinking water. In case the body is not immune to it, diarrhea or gastroenteritis can be experienced. The presence of coliform bacteria can indicate the contamination of water by other microbes. Coliforms act as indicators of possible contamination. Giardia lamblia is another type of waterborne parasite and causes giardiasis. Giardiasis is a disease that causes diarrhea, abdominal cramps, weight loss, and nausea for a week and, in some cases, can also cause chronic infection. Cryptosporidium is a parasite that causes the disease of cryptosporidiosis, which has been seen in the past five years. Over 400,000 people were ill with the disease after drinking contaminated water in 1993. The symptoms can occur within two to 10 days after the infection; symptoms include headache, diarrhea, nausea, vomiting, and fever.

Other sources of contaminants in drinking water are disinfection by-products such as bromate, chlorite, and haloacetic acids, which can increase risk of cancer and nervous system effects with long-term exposure in adults, infants, and young children. Other disinfectant contaminants found in drinking water are chloramines, which cause eye and nose irritation, stomach discomfort, and anemia, and chlorine dioxide, which also affects the nervous system in infants and young adults. Among the inorganic chemicals, arsenic, antimony, barium, beryllium, cadmium, chromium, copper, fluoride, lead, mercury, nitrite, selenium, and thallium are sources of contaminants in drinking water that have serious potential health effects such as increase in blood cholesterol, decrease in blood sugar, skin damage, cancer, kidney damage, allergic dermatitis, nerve damage, thyroid problems, and high blood pressure from long-term exposure. Organic chemicals enter the drinking water system either during wastewater treatment, leakage from linings of water storage tanks and distribution lines, discharges from factories, or runoff from herbicides used on row crops.

Contaminants in Soil

Pollution is caused in soil by the presence of human-made chemicals as either solid or liquid hazardous substances mixed with soil matter. Contaminants in the soil can hurt plants, animals, and humans and have adverse impacts on their health. Animals and humans can ingest, inhale, or touch contaminated soil or eat plants that are already affected by contamination. The main source of contamination in soils is from industrial wastes, underground storage tanks, application of pesticides, oil and fuel dumping, leaching of waste from landfills, and disposal of coal ash. Large quantities of trace metals from coal combustion, ash residues, and wastage of commercial products are other sources of contamination in soil. A trace metal found in municipal sewage sludge can easily contaminate the soil. Municipal sewage embodies an important source of metal contamination in land. There are health risk concerns with soil contamination in terms of direct contact with contaminated soil or any vapors from the contaminated soil and contamination of water underlying the contaminated soil. Human consumption from groundwater aquifers contaminated by infiltration from contaminated soil, inhalation of vaporized soil contaminants, or direct contact with soil have health consequences. Health consequences from exposure to soil contamination can vary depending on the level of exposure, the type of pollutant, and the pathway of attachment, but any chronic exposure to chromium, petroleum, pesticides, lead, and other metals can cause congenital disorders and chronic health conditions.

Sources of Soil Contamination

The property of soil varies from place to place and can be easily influenced by many factors. Human activities put the most harmful substances in the soil. The properties of soil are affected by past and current land uses. For instance, because of poor storage practices or spillage in gas stations and mechanics' garages, there are contaminants such as fuel and lubricants that enter the soil inadvertently. The properties of soil can also be contaminated by indirect sources such as rain runoff from roads and buildings, which can introduce heavy metals such as mercury and lead. Some general sources of contamination in soil are paint, high traffic areas, treated lumber, burning wastes, manure, coal ash, sewage sludge, petroleum spills, commercial/industrial site use, and pesticides. Through these general sources, lead, zinc, PAHs (polycyclic aromatic hydrocarbons), arsenic, copper, dioxins, sulfur, cadmium, benzene, toluene, xylene, heavy metals, and mercury are introduced into soil.

Acceptable Levels of Contamination in Soil

Certain chemicals naturally exist in soil as components of minerals, but the soil contaminants in urban settings exceed the natural level. The evaluation and cleanup of contaminated soil is based on soil screening levels (SSLs), determined by the EPA. Since there is no single standard that can define the acceptable level of contaminants in soil, SSLs are a general guide in directing resources for site evaluation and cleanups. Of the industrial, residential, and agricultural use standards, the agricultural standard is the strictest, since the contaminants present in soil have to be at minimal levels to grow food. Excavation of soil from the ground with the purpose of treating or disposal, containment of soil in place, and soil treatment in place are three general approaches to cleaning up contaminated soil. In some cases, contaminants are flushed out of the soil using water and chemical solvents, or encapsulated by adding materials to the soil to prevent chemicals from spreading.

Contamination in the Air

The action of environmental contamination with human-made or natural contaminants is pollution. By introduction of contaminants into an environment, the ecosystem becomes unstable. The discomfort, disorder, and instability in an environment caused by introduction of contaminants by release of chemicals and particulates into atmosphere is called air pollution. Pollution in the air can be odorless and colorless or can be apparent in the form of smog. The main contributors to pollution are industries. Most of the greenhouse gases are released into the atmosphere by factories. Many of these gases and the gases released from burning fossil fuel are harmful and have significant health and environmental effects. The Big Six air pollutants are carbon dioxide, carbon monoxide, sulfur oxide, nitrogen oxide, hydrocarbons, and particulates. These gases are primary pollutants and can affect the environment directly. Other gases like nitrogen oxide and sulfur are secondary pollutants and can react with other chemicals like water and become more harmful to the environment in the form of acid rain in the atmosphere. Pollution can affect everyone on Earth and is a global crisis.

Effects of Pollution on Human Health

Adverse air quality can cause respiratory disease, congestion, and cardiovascular disease. Air pollution can be a nuisance and can be injurious to human life, animals, and even vegetation. All over the world are premature deaths resulting from air pollution, and studies show that more than 50,000 people die in the United States annually because of air pollution. Air quality not only affects the health of the environment and the health of the community but also has a direct influence on our lifestyle. Therefore, the quality of life depends on the pressures on our air and our responses to it. Short-term and long-term exposure to greenhouse gases has diverse health effects on humans. Short-term exposure to carbon monoxide causes the carrying capacity of oxygen in the blood to reduce and can cause damage to the nervous system and the heart. Over time, exposure to ozone gas can cause decrease in lung function and increase the chances of asthma and other respiratory symptoms. Exposure for a short period of time to nitrogen oxide causes respiratory illnesses in children; respiratory infection in adults can result after long-term exposure. Nitrogen dioxide can also cause death in plants and damage to crops. These gases are formed when fuels are burned by human in large cities.

Possible Approaches for Crisis Managers

Environmental issues are diverse, and different factors or situations can lead to an environmental crisis. Therefore, it is very important to call for multidimensional approaches in order to combat any environmental perturbations. In general, there are two ways to approach crises as unfortunate events: (1) keeping events from reoccurring and (2) lessening the impact of the crisis by softening or mitigating them. Although a crisis is a low-probability event, it can have a high-damage impact; therefore, being aware of the scope of the vastly negative impacts of various crises should be the goal of the environmental crisis manager. As crisis prevention is a broader concept of pre-crisis management and can be used as type of control management, the three broad areas where crisis management can contribute to the prevention of any environmental crisis are to (1) proactively address the underlying systemic causes of a potential crisis, (2) establish signal mechanisms to detect a foreseen crisis, and (3) learn and understand the ongoing basis of any crisis. Since the fundamental step of combating environmental crises is to recognize the warning signs or trends of events and respond to them properly and promptly, learning from crisis and preparation are the keys to success.

In dealing with an environmental crisis that can pose an extreme danger to not only the environment but also public health, it is very important for managers to effectively deal with every aspect of the crisis and be able to identify audiences who are affected by the event. In planning for crisis management, managers classify the potential crisis situations, identify those who would be affected, and minimize damage by testing formulated strategies and tactics for dealing with potential crises.

Epidemics

Epidemics can be defined as disease outbreaks that occur within given geographic areas, such as communities, villages, states, or territories, that spread to other areas. Epidemics can be caused by microorganisms (germs) in the form of bacteria, viruses, fungi, protozoans, or parasites.

Comparably, endemics are diseases that occur routinely within villages, states, or small regions. For instance, the plague is endemic to the mountainous regions of the western United States, and malaria is endemic to the tropical areas of the world. Endemic diseases can easily spread to other regions by various means. These include by travelers, through commerce, or by animals. Additionally, viruses have the ability to mutate once they encounter environmental changes or combine with other strains inside a host.

Epidemics can easily become pandemics if the outbreak of disease affects larger regions or other areas of the world. These outbreaks may involve any number of diseases, including influenza, severe acute respiratory syndrome (SARS), malaria, tuberculosis, and smallpox.

Origins and Outbreaks

Humankind has documented evidence of disease outbreaks occurring throughout the world since the development of written records. Hippocrates documented an outbreak of deadly influenza occurring throughout Greece and neighboring countries in 412 B.C.E. An outbreak of leprosy also occurred during this time and has been documented in both literary and religious works. Smallpox affected the New World just as George Washington and the Continental army battled British troops.

Both sides suffered tremendous losses from this epidemic. Physicians developed crude methods of inoculating both soldiers and the public by using variolation. These physicians captured matter from the pustule of an infected person and placed it beneath the skin of an unaffected person, potentially causing immunity. This also served to reduce the size of the outbreak, thereby potentially saving thousands of lives.

A majority of disease outbreaks remain localized (endemic) or regionalized (epidemic). However, others can spread globally, which is defined as a pandemic. Disease outbreaks typically follow a cycle, beginning with infection of a population, either on a small or large scale, severe illness, or eventual death of the host. A host can be most any animal, from migratory waterfowl to humans. Viruses often die themselves once they have run their course. Humans have the ability to develop immunity to bacteria or virus strains once they have become infected and survived the illness. Unfortunately, bacteria or viruses have the ability to mutate or evolve into new, more deadly strains. Humans typically do not have immunity from these new strains, which can potentially lead to an epidemic. Examples include the 1918 Spanish influenza, which begin as an epidemic and eventually resulted in over 40 million deaths. Similar epidemics occurred in 1957 and 1968. Most recently, an outbreak of avian influenza (H5N1) and swine influenza (H1N1) occurred in 2009 and 2010. Each of these is a variation of influenza Type A.

Epidemics not only affect individuals from a medical standpoint but can also affect them economically. Because commerce is totally dependent on people, the economy can quickly become stagnant if people are not purchasing goods and services. This can lead to a global recession. Moreover, people are needed to sell these goods, operate stores, and provide routine services such as fuel and water delivery.

During the 1918 influenza outbreak, manufacturing processes were not as technologically advanced as they are today but instead were heavily dependent on human beings. If people were sick, products could not be manufactured. In the United States, hundreds of stores, utilities, shops, and public services closed or came to a halt. Workers were ill and unable to report to work; some were simply afraid of becoming infected themselves, so they just stayed home. In some cases, local officials directed that theaters, schools, stores, and other public places be closed in an attempt to prevent the spread of disease to others within the community. This resulted in huge economic losses. It was not uncommon for entire families to perish during the outbreak. Many small businesses never reopened because there was no one left to manage the business. Routine services such as utilities and ice and food deliveries often stopped for days as trained workers became ill and could not report for work or died. Meetings such as church services, community events, and fairs were canceled because of the outbreak. Schools and universities canceled classes because students and faculty either could not report for classes or refused to attend for fear of contracting the flu. Hospitals quickly became overwhelmed with patients and had to turn them away. Tent hospitals were established in order to treat the most severe patients. In rural areas where many could not afford medical care, they simply treated family members as best they could and hoped for the best. Funeral homes become so overwhelmed they had to hold multiple funerals each day just to keep up.

Preparedness Efforts

The World Health Organization (WHO) joined forces with the Centers for Disease Control and Prevention (CDC), the International Society for Disease Surveillance (ISDS), and private health organizations to develop syndromic surveillance standards and guidelines. Several outbreak indicators have been developed using these standards and guidelines. These indicators include but are not limited to monitoring individuals for fevers, dysphasia, respiratory problems, skin lesions, and other associated medical problems. Once the medical signs and symptoms associated with a possible outbreak are recognized, medical and scientific teams examine these sick individuals and then confirm their illness using laboratory tests. Government agencies and public health officials in the affected area then notify their counterparts throughout the world in an effort to identify similar outbreaks. At this point, public health officials may officially designate the outbreak as an epidemic. However, epidemics can easily become pandemics once the outbreak affects larger regions or other areas of the world. Because the historical epicenters of the largest disease outbreaks have occurred in southeast Asia, the WHO and its partners have focused much of their attention on this region of the world.

Response

Upon recognition and confirmation of a disease outbreak, public health officials attempt to vaccinate the affected community in an effort to prevent the outbreak from spreading. Moreover, officials may initiate efforts such as social distancing, school closures, and encouragement of work-from-home strategies. Crisis managers may work with private-sector partners to initiate specialized services such as call-ahead shopping and curbside pickup. Neighboring communities, villages, and towns are monitored for similar illnesses, and treatment is provided as needed. Public health and government officials may monitor travelers for the signs and symptoms of the outbreak. These efforts may include using thermal imaging cameras to detect high fevers or simply observing passengers for coughing, runny noses, or signs of malaise. Travelers displaying these signs or symptoms may be detained and quarantined as means of reducing exposure to others. Travel restrictions may be put into place in order to contain the outbreak. Public health officials also notify key stakeholders and other health officials in an effort to identify additional outbreaks. These regionalized and cross-border partnerships among world organizations, governments, and public health officials have led to the reduction and prevention of outbreaks in other countries. During the 2009–10 H1N1/H5N1 outbreak, public health leaders in both Asia and Mexico notified World Health Organization officials whenever they detected a new emerging potential disease outbreak. This early warning system allowed physicians, crisis managers, government leaders, and scientists to develop a response before the outbreak became a pandemic.

Ethnic Cleansing

Although instances of ethnic cleansing since World War II, and especially during the last five decades of the 20th century, have often figured prominently in newspapers and journalistic accounts, including infamous cases such as Rwanda, Bosnia, Darfur, and the Indian partition, it remains a controversial subject. In each case, a dominant, well-armed group can inflict devastating harm, expulsion, relocation, and mass murder in an effort to eliminate the presence of a suspect targeted group from a territorial area as part of an overall political campaign to "purify" the land in dispute. The central issue has been sharply defined during those years by international agreements and efforts by the United Nations to define what ethnic cleansing really is.

Based on a wide variety of conventional definitions, ethnic cleansing is most often understood to mean the following:

- The systematic elimination of an ethnic group or groups from a region or society, as by deportation, forced emigration, or genocide
- A mixture of forced emigration and population exchange with elements of territorial deportation and targeted killing
- The physical and political expulsion of an "undesirable" population from a given territory because of religious or ethnic discrimination; political, strategic, or ideological considerations; or a combination of these factors

A more formal definition arose in the 1948 Convention for the Prevention and the Punishment of the Crime of Genocide. That convention said genocide was any of the following acts committed with intent to destroy, in whole or in part, a national, ethnic, racial, or religious group, as by (1) killing members of the group, (2) causing serious bodily or mental harm to members of the group, (3) deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part, (4) imposing measures intended to prevent births within the group, and (5) forcibly transferring children of the group to another group.

It is important to note that ethnic cleansing often includes indiscriminate killing of targeted ethnic, racial, cultural, or religious groups, but such activity by itself does not necessarily elevate it to the formal legal definition of genocide. This is an irritant both to the victims of ethnic cleansing and to those seeking to punish and indict those leaders who are responsible for directing or authorizing ethnic cleansing.

The strongest efforts have been aimed at punishing those who are responsible for genocide, primarily through individual criminal tribunals organized for that specific purpose. Even these endeavors—in Rwanda and the former Yugoslavia—have come about only in this decade. Those responsible for recognized acts of genocide over the last three decades have gone unpunished, despite demands from survivors and witnesses.

The United Nations Commission of Experts' report on ethnic cleansing in Bosnia issued in 1994 described ethnic cleansing as "the planned deliberate removal from a specific territory, persons of a particular ethnic group by external force or intimidation, in order to render that area ethnically homogenous," which it based on "the many reports describing the policy and practices conducted in the former Yugoslavia." The commission went on to state that, "ethnic cleansing has been carried out by means of murder, torture, arbitrary arrest and detention, extra-judicial executions, rape and sexual assaults, confinement of civilian population in ghetto areas, forcible removal, displacement and deportation of civilian population, deliberate military attacks or threats of attacks on civilians and civilian areas, and wanton destruction of property. Those practices constitute crimes against humanity and can be assimilated to specific war crimes. Furthermore, such acts could ultimately also fall within the meaning of the 1948 Genocide Convention."

The UN Commission of Experts (established pursuant to UN Security Council Resolution 780) held that the practices associated with ethnic cleansing "constitute crimes against humanity and can be assimilated to specific war crimes. Furthermore ... such acts could also fall within the meaning of the Genocide Convention." The UN General Assembly condemned "ethnic cleansing" and racial hatred in a 1992 resolution, saying it is similar to forced deportation or "population transfer" whereas genocide is the "intentional murder of part or all of a particular ethnic, religious, or national group." The central idea in ethnic cleansing is "to get people to move, and the means used to this end range from the legal to the semi-legal."

The 1994 UN special experts' report on Bosnia referred to "the abhorrent policy of 'ethnic cleansing,' which is a form of genocide," as being carried on in Bosnia and Herzegovina. This was the specific campaign by Serbs against Bosniak Muslims. The report went on to say that ethnic cleansing can only be a form of genocide within the meaning of the 1948 Convention, if it corresponds to or falls within one of the categories of acts prohibited by Article II of the Convention:

> Neither the intent, as a matter of policy, to render an area 'ethnically homogeneous,' nor the operations that may be carried out to implement such policy, can as such be designated as genocide: the intent that characterizes genocide is 'to destroy, in whole or in part' a particular group, and deportation or displacement of the members of a group, even if effected by force, is not necessarily equivalent to destruction of that group, nor is such destruction an automatic consequence of the displacement. This is not to say that acts described as 'ethnic cleansing' may never constitute genocide, if they are such as to be characterized as, for example, 'deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part,' contrary to Article II, paragraph (c), of the Convention, provided such action is carried out with the necessary specific intent … that is to say with a view to the destruction of the group.

Strictly speaking, there is no formal legal definition of ethnic cleansing yet agreed to by an international body. However, ethnic cleansing in the broad sense—the forcible deportation of a population—is defined by UN agencies as a crime against humanity under the statutes of both the International Criminal Court (ICC) and the International Criminal Tribunal for the Former Yugoslavia. Holding those accountable for directing and authorizing ethnic cleansing has met with limited success.

Historically, instances of ethnic cleansing can be found going back centuries, to at least 700 B.C.E. by various kingdoms, leaders, and conquering groups in biblical times. Most well-recorded instances seem to start significantly after 700 C.E. and move forward, as a mix of historical accounts take note of this practice without benefit of an agreed definition. For example, while many would find this instance at variance with our definition, some could argue that within two centuries following the birth of Islam, there was an aggressive and wide-ranging campaign of conquest and systematic elimination of native males to compel their widows to revert to Islam. Forced conversion by the sword, which arguably imposed ruthless and totalitarian requirements on conquered populations, typically made its victims choose between Islam and death. In a matter of 200 years, Iraq, Syria, Palestine, Egypt, and most of what is now the north African Levant, which had historically been non-Arab, became Arab-speaking Muslim societies.

There is ample evidence of Jews being expelled from England (1290), France (1306), Hungary (1349–60), Provence (1394 and 1490), Austria (1421), Lithuania (1445), Cracow (1494), Portugal (1497), and numerous German principalities at various times. More recently, during the 20th century, other instances of ethnic cleansing noted in history include the following:

- The controversy surrounding Turkish efforts to exterminate Armenians in 1915
- Japanese imperial military extermination and destruction of native Chinese populations in Harbin during the late 1930s
- Croatian plans to purge Croatia of Serbs during World War II by killing one-third, expelling one-third, and assimilating the rest
- An Indian military campaign in 1947 that caused 6 million Muslims to flee risks of genocide, relocating to what became Pakistan and, in turn out of fear of retribution, 5 million Hindus and Sikhs fleeing what became Pakistan into India

In 2012, as the infamous Arab Spring unfolded in Tunisia, Libya, and Egypt, there were some reported instances of ethnic cleansing similar to the kind being waged against dark-skinned peoples in Darfur Sudan. In a June 21 *Wall Street Journal* article covering the dissolution of Muammar Gaddafi's Libya, reporter Sam Dagher described Tawergha as a town inhabited mostly by black Libyans, a legacy of its 19th-century origins as a transit town in the slave trade. He related the comments one of the rebel commanders from the rebel Misrata brigade as follows:

> Ibrahim al-Halbous, a rebel commander leading the fight near Tawergha, says all remaining residents should leave [at] once if his fighters capture the town. "They should pack up," Mr. Halbous said. "Tawergha no longer exists, only Misrata."

Here again, the trail of evidence regarding ethnic cleansing is more anecdotal than factual but nevertheless illustrates the continuing dilemma of anyone who would allege that ethnic cleansing is actually taking place. The lesson of history is that brutal and bloody civil wars, humanitarian crises, and guerrilla campaigns for decades to come in the 21st century may include instances of ethnic cleansing whether they are reported or not. History exemplifies this violent trend that reflects a tendency to use this form of lethal leverage as part of a calculated political effort to permanently alter the landscape, history, and culture of an area.

Evacuation

Evacuation means to move from a place of danger to a place that is safe. It is conceptualized in multiple ways within the literature. Ideally, evacuation should involve using the quickest path to safety. Evacuations are more common than the public realizes. Each year, issues such as chemical releases, wildfires, floods, and even snowstorms force the public to evacuate their homes. Moreover, in a heat wave, often vulnerable populations are moved from their homes to "cooling stations" with the goal of protecting them from brownouts or air conditioner malfunctions, simply to ensure that they are not adversely affected by the extreme temperatures.

Evacuations can be either short term or long term. Short-term evacuations require leaving for safety for a short period of time, to enough distance from danger. In the event of such an occurrence, directions from local emergency management officials are provided. Long-term evacuations may cause individuals to experience displacement or the inability to return to their homes or communities.

Community or individual planning for evacuation has become an integral part of crisis and crisis preparedness. Described as crisis relocation, temporary displacement, or evacuation, much planning for possible evacuation in future nuclear wartime situations has been undertaken in addition to planning for natural and human-made disasters. Planning in the literature is sometimes confounded with preparedness and other times treated as its own construct. Preparedness in the form of general knowledge and information should facilitate evacuation by enabling more appropriate response behaviors. It essentially refers to the readiness of a political jurisdiction to react to threats from the environment in a way that reduces the negative consequences of impact to the health and safety of at-risk individuals. Therefore, preparedness should be treated as distinct from evacuation planning. Planning and preparedness are similar in their attempt to reduce harm and the ability of both to be undertaken at the individual or group level.

The importance of evacuation appears obvious, given that its advantages are seldom explicitly discussed or enumerated in crisis and disaster research. It is an obvious pre-crisis strategy for mitigating the negative consequences associated with a particular extreme event. Pre-crisis evacuation may also serve to strengthen morale because it has the ability to reinforce the beliefs of citizens that authorities are looking out for their interests during a crisis. Post-impact evacuation may enable victims to more easily obtain necessities such as food, water, medication, and shelter.

When community evacuation becomes necessary, it is common for the order to come from local officials. Moreover, the order to evacuate is usually accompanied by detailed instructions. These instructions are updated and repeated by the mass media. In some crises, other warning methods, such as sirens or telephone calls (including what is known as reverse 911) or text messages, are also used. Agencies at several levels of government offer literature and recommendations for evacuation planning. Some of the most common recommendations in the United States include advice such as keeping adequate gas in a primary vehicle for an evacuation. Support is given for this procedure because gas stations may be closed during an emergency or it may be impossible for gas stations to distribute gas during a power outage.

If an individual does not own a car, he/she is encouraged to make arrangements to facilitate evacuation. Additionally, people are encouraged to have a disaster supply kit for the event of an evacuation, sometimes referred to as a bug-out-bag, 72-hour kit, or grab-bag. Recommendations for the contents of a kit include three days of food, water, and clothing. Batteries, radio, first aid supplies, tools, medications, currency, and needed documents are also suggested components.

Evacuation Training and Preparation

Training and planning for evacuations is generally recognized as one of the most important elements to an effective evacuation and response. Effective evacuations do not rely only on the knowledge and application of technical expertise or emergency operation procedures and logistics; they also rely on the nontechnical personnel involved in maintaining communication systems, directions, and structures. Finally, successful evacuations depend upon a well-informed citizenry. Evacuation planning is often limited and of poor quality. Training and preparation are generally required to improve skills for an evacuation. Skills needed for a successful evacuation include decision making, communication, leadership, and coordination. Training results in more effective and efficient decision making, accelerated proficiency, and the development of expertise in individuals and teams, all of which are issues particularly crucial in complex, highly uncertain, critical, and hazardous real-life situations.

Training and evacuation preparation tend to take the form of exercises, drills, informational seminars, and public service announcements. Such events are usually sponsored by local emergency response teams or regional coordinating units. Involvement of local radio stations can provide benefits to the community and is useful to radio station personnel in understanding community response. Moreover, without training, innovation and emergent organization in response to a crisis are less likely to occur. Exercises and drills also allow participants to gauge how personnel and equipment will work in a specific environment.

The public generally makes risk assessments and decisions to evacuate based on sensory perception. Thus, one advantage of training and preparation is when the general public is taken off guard or underestimated the risk—even if they begin evacuation, their chance of success is strong.

For some crises that require evacuation, the risks associated are typically visible and relatively well understood, such as natural disasters. Events such as terrorism are typically less understood, causing individuals to question whether to evacuate or shelter-in-place.

Evacuation Coordination and Crisis

The issue of interorganizational coordination is also associated with the success or failure of an evacuation. Coordination is based largely on precrisis understanding facilitated by planning and training. In other words, activities such as exercises can aid in multi-organizational coordination. In a large-scale crisis, coordination of communication and emergency response is required because the capacity of individual emergency response agencies is limited. Moreover, unanticipated problems may arise, making response even more difficult; thus, coordination among several emergency response agencies is often necessary to manage the evacuation.

Researchers have suggested that the media play an important role in evacuation coordination. First, responders define and portray an event as a crisis by using their perspectives and experiences. Media frames are created by journalists and reporters, and these influence subsequent interpretations of the crisis. Moreover, first responders and managers of first responders rely on media coverage for information in order to make decisions about response strategies, logistics, and operations in the event of an evacuation. They also depend on the media to inform the larger public about the evacuation and changes in procedures and conditions. During the actual evacuation, radio may be the only broadcast medium individuals can receive.

Radio stations are expected to aid in the communication and coordination needs of a community during a crisis and at times even go above this expectation. In their mission to serve the public need, local stations will often replace regular programming with continuous live coverage of a crisis. Such coverage is likely to include accounts from listeners, reports from affected areas, instructions, and statements from public officials. Radio can also be used as a mechanism for proactively recruiting of volunteers to help in evacuations and for reactively assisting in disaster logistics and relief activities.

For example, in 1994, Louisville, Kentucky, was hit with record snowfall that shut the city down for almost a week. WHAS 840-AM radio made an effort to coordinate local response efforts, such as mobilizing individuals with 4×4 vehicles. Another instance occurred when WHAS broadcast a story about a local 3-year-old girl in need of a liver transplant. A donor was found in Omaha, Nebraska, but the streets of Louisville were covered with 16 inches of snow and the local airport was closed. After WHAS broadcast the story, over 200 people arrived with snow shovels to clear a helicopter landing spot in a church parking lot near the home of the young girl. Also, shortly after the broadcast, volunteers arrived to plow the local runway so the helicopter could land safely at the hospital. On a day when most folks could not get down the block, the young girl got to Omaha in time. Radio was a needed and effective medium for coordinating the evacuation of one person during the storm.

Organizations almost always rely on extensive relationships and networks of external groups and agencies during an evacuation. The issue of evacuation coordination is complex, and organizations and agencies face many impediments to effectively working together during the stress and uncertainty of a crisis. Lack of coordination during an evacuation may be attributed to factors such as misunderstandings among organizations, failure to fully utilize equipment and personnel, omission of essential tasks, and overly taxed organizations. The novelty of crises and other extreme events also makes coordination necessary but challenging. It has been noted that organizations with experience working together before a crisis experience fewer problems during crises. Thus, organizations working together in evacuation training or exercises may be better prepared to improve disaster coordination. Increasingly important to the successful management of disasters are emergent multiorganizational networks, or EMONs. EMONs comprise personnel and resources drawn from governmental, quasi-governmental, and private organizations. EMONs must deal with unfamiliar personnel, communication breakdowns, and ambiguity in the emergent authority structure.

An injured woman tries to calm herself just before takeoff during a U.S. Navy medical evacuation in the aftermath of Hurricane Felix in Nicaragua, September 7, 2007.

Evacuating Individuals With Special Needs

The National Fire Protection Association (NFPA) classifies five general categories of disabilities to consider when making evacuation plans. These are mobility impairments, visual impairments, hearing impairments, speech impairments, and cognitive impairments. When making evacuation plans for these groups, questions to consider include how will they obtain the notification of evacuation, how will they find the evacuation route, and can they evacuate on their own or will they need assistance? Low-mobility groups, the elderly, and individuals with disabilities are some of many groups that are often left out of the evacuation planning process. Individuals in such groups may be unable to react quickly or to take proper protective actions to evacuate and therefore may be more likely to experience harm.

The Federal Emergency Management Agency (FEMA) has attempted to integrate its guidance to crisis managers on issues related to disability and other functional needs in the adoption of a new model called Functional Need Support Service (FNSS). This model works well with the housing of functional needs populations. Specifically, the model encourages stakeholder participation in the planning and implementation process. The best information available to assist crisis managers in developing crisis plans that accommodate functional needs can be found within the local community itself. Therefore, crisis planning that is more local is seen as more responsive to local needs.

In order to persuade people to engage in evacuation planning, individuals first must be convinced that evacuating will lead them to safety (response efficacy) and must believe that they can take the recommended action (self-efficacy). This is another barrier to planning for individuals with special needs. The self-efficacy problems of the elderly, therefore, revolve around reappraisals and misappraisals of their capabilities. Many physical capacities also decrease with age, requiring reappraisals of self-efficacy for activities in which the mediating biological functions have been significantly affected. Variability in self-efficacy is in part determined by whom the elderly compare themselves against. Those who measure their capabilities against people their age are less likely to view themselves as declining; however, when the elderly populations see evacuation behavior being modeled by only younger people, the motivation to engage in planning decreases. When individuals observe a model with similar characteristics performing a task successfully, this experience helps bolster their own self-efficacy.

Case Study: Evacuation During the 2003 E2 Nightclub Disaster in Chicago, Illinois

At the time of the crisis, Epitome restaurant was located at 2347 South Michigan Avenue in Chicago. On the second floor of the restaurant is the E2 nightclub. In the early morning hours of February, 17, 2003, a crowd of over 1,000 patrons was asphyxiated by mace that a security guard working for E2 nightclub had sprayed in attempts to break up an altercation. As the crowd began running toward the only exit available, hundreds of people were caught in a 6-foot-high human stampede. Twenty-one people lost their lives due to trampling.

A major factor that contributed to the stampede was the construction of the E2 nightclub. The E2 is located at the south entrance of the Epitome restaurant. However, there is only one main staircase leading up to the club. Between the staircase and the entrance to the club is a narrow corridor. Once inside the nightclub, there are additional staircases leading to VIP boxes, but the only way to exit the boxes is to enter the assembly area of E2. In other words, there is no stairway leading from the VIP boxes to the ground floor exit. Building inspections conducted six months prior to the tragedy had maintained an order not to occupy the E2 nightclub. However, this mandatory order did not deter E2's management from throwing events. Also, no occupancy placard was enforced for the nightclub because E2's operators informed the Department of Buildings that the nightclub was not open for business.

A significant number of complaints were also filed against E2 in the years prior to the stampede. Most of these were violations regarded building codes, liquor license violations, and serving to minors. Overall, 11 building code complaints were issued against the owners of E2 and Epitome restaurant—the most serious dealt with structural issues with roof trusses and the construction of VIP rooms on those trusses. After the complaints were brought to court on July 19, 2002, only one violation was granted, which resulted in a court order not to occupy the second floor. However, E2 management did not comply and continued to throw parties in the nightclub. Also, the Chicago Police Department was never notified of the order, even though it made frequent visits to the nightclub after the court order was enforced.

The Chicago liquor commission voiced unclear regulations that governed liquor licenses, which also contributed to the onset of the crisis. La Mirage Studio Ltd. d.b.a. Epitome E2 (the operating name for the Epitome restaurant and the E2 nightclub) needed two liquor licenses to sell alcohol in both locations. The liquor commission did not clearly indicate, however, that because E2 and Epitome were considered two separate facilities, they needed two separate liquor licenses. Also, the operators of La Mirage Studio did not request clarification as to the scale of the liquor license regulations. Therefore, E2 continued to serve liquor even though Epitome was the only facility displaying a liquor license. This persistent lack of responsibility of the operators of E2 and Chicago's agencies resulted in one of the worst tragedies Chicago has ever seen. Thus, lack of evacuation planning, evacuation routes, and knowledge, coupled with repeat system failures, created an easily preventable crisis.

Other Types of Evacuations

Communities are not the only level of analysis by which evacuations occur; planned evacuations exist for airplanes, boats, public venues, and buildings, often called small-scale evacuations. Evacuation procedures are covered on all commercial U.S. airline flights. Additionally, shelter-in-place, or horizontal evacuation, is also well represented in the literature. This type of evacuation is a short-term strategy for protection from a risk. The strategy is not new but did gain more public attention during discussion of the prospect of a "dirty bomb" or other related chemical, radiological, and biological emergencies. Shelter-in-place means selecting a small interior room with no or few windows and taking refuge there. Shelter-in-place can even be applied to individuals in a vehicle. In such a situation, individuals are instructed to turn off their automobile engine and close windows and vents. If possible, they should seal the vents with duct tape and listen to the radio regularly for emergency instructions.

After the first bombing of the World Trade Center in 1993, evacuation planning and practice efforts in the center increased. The building evacuation that took place in the World Trade Center on September 11, 2001, was for the most part considered successful. It was estimated that on the day of the attacks, the number of individuals in the towers was between 10,000 and 15,000. The success of the evacuation has in large part been attributed to the enhancements and evacuation drills that followed the 1993 World Trade Center bombing. These enhancements included increased evacuation drills, adding battery-powered lights and glow-in-the-dark paint in the stairwells, the appointment and training of floor marshals to facilitate the evacuation process, and redesigned emergency plans.

Crowd Safety and Survival

In the last century, there have been numerous accounts of human disasters resulting from unforeseen conditions such as building fires, trampling, stampeding, and suffocation. With no avenue of escape, humans experience extreme panic, which results in terrible injuries and death by human hands. Academic scholarship has shown that concert halls, sports arenas, assemblies, stadiums, and nightclubs are prone to accidents when overcrowding is part of the culture. Thus, managing large numbers of crowds has become an extremely complex endeavor. Crisis management literature has attempted to tackle these aforementioned problems by focusing on two parallel approaches to disaster management: contingency-based and strategic-based approaches to evacuations.

The contingency-based approach is concerned with reactive modes to dealing with crisis events, such as evacuations and/or media and medical responses. This approach is more technical in nature, focusing on nonhuman elements that may enhance safety in the case of mass evacuation. In large sports arenas, for example, crisis management consultants provide technical information such as passageway and corridor widths that can withstand large crowds of people. Also, providing businesses such as nightclubs with maximum capacity occupancy placards and proper liquor distribution can help ensure crowd safety. These scholars and practitioners are typically concerned with the cost and control aspects of crisis management. The strategic-based approach to disaster management examines crisis as a preventable activity, one that works to instill change in the organizing mind-set. This approach is more organic in nature and focuses on communications, cultural change, and reconfiguration. The assumption of this approach is that any taken-for-granted beliefs about the notions of safety and crowd control can and should be replaced with new and innovative strategies, thus ridding any technical or regulatory behavior. However, evacuations are not always planned or initiated by crowd safety control practitioners. As is evident in much scholarly and documented research, human stampeding is an inertia that forestalls any possible safety measures.

Human Stampedes

Public spaces bring a large and diverse number of people together. Whether it is a city block, a musical performance, or a parade, people gather in tight-knit spaces. Such diversity in crowds can be a rewarding and celebratory experience. People gather to bring in the New Year or to support a presidential candidate. However, crowds also gather to protest or express their own interests with anger and outrage. When considering the latter, evacuating can be a tricky and often dangerous experience. Individuals who gather in public spaces are often strangers with their own values, beliefs, and interests at heart. From a biological standpoint, these personal interests activate a survival response, often without concern for others. The reaction for one's own survival also supersedes any plans for evacuation safety. As a result, people experience high levels of anxiety, panic, and irrational behavior. When such panic ensues, individuals' attention to escape routes such as side exits is typically minimized. Numerous accounts of human stampedes can make these notions more concrete.

In 2000 alone, there were over 12 major crowd disasters documented in venues such as stadiums, nightclubs, holy places, and camps. Also, since the early 20th century, the United Kingdom has documented countless numbers of football stadium disasters. Each crowd gathering resulted in major injuries and even death of patrons. Tear gas, oversold stadiums, overexcited fans, and overcrowding were among the many instigators of evacuation disasters. Such panic situations result in the death of people who are trampled and crushed by other individuals. Panic stampedes are also documented as one of the most tragic collective behaviors. One particular human stampede that occurred in the United States is examined on page 384 for further clarification.

Exercises

A crisis is recognized as an abnormal situation that is beyond the scope of everyday activities and that might threaten the operation, safety, and reputation of an organization. In order to prepare for, respond to, and recover from modern crises, organizations should establish both crisis management and business continuity plans. Once these plans have been written, exercises should be used to test the effectiveness of the entire cycle of the crisis and business continuity management processes. Exercises can be used to ensure that staff are aware of and understand the existence of plans and are familiar with the proposed arrangements. Exercises can be used to rehearse, test, revise, and improve the plans.

Definition

Exercises have been widely used in complex and diverse disciplines, for example, hunting and fighting skills, airplane performance simulations, and current classroom exercises for school students. Canada, Australia, and the United States tend to use drills, while European countries refer to them as simulations. Exercises can be defined as one of the training methods that represent a selected feature of a real and dynamic situation, replicating it within a risk-free environment within which trainees are placed to cope with particular challenges that improve learning outcomes.

The United Kingdom (UK) Cabinet Office describes an exercise as the simulation of an emergency that is used to "validate plans (validation);

to develop staff competencies and to give them practice in carrying out their roles in the plans (training); and to test well-established procedures (testing)." Ideally, those involved in the exercises should be trained beforehand. At the same time, the U.S. Federal Emergency Management Agency (FEMA) also defines an exercise as "an activity designed to promote preparations for emergency situations in order to test operations, policies, plans, procedures or equipment, or to demonstrate the capability to respond to a crisis." In any case, the aim of exercises is to use more frequent, constant, and broad variety types of training methods to improve and retain staff knowledge and skills that are related to preparing for and responding to accidental or crisis situations.

The UK Home Office categorizes exercises into four types: (1) discussion-based seminar and/or scenarios, (2) tabletop (multidiscipline, single-agency, and management-level role-play), (3) control post, and (4) live exercises (small-scale-single-agency to test one component or full-scale-multi-agency to test the whole response to an incident). The FEMA further divides exercises into drills, functions, and full-scale. There is also a trend to include information technology (IT)-based exercises in the discussion.

Skills to Be Trained During an Exercise

An exercise is a useful tool to provide repeated learning by individuals, teams, and organizations involved in a crisis event for how to prevent or deal with disruptive situations. Exercises also provide a platform for participants to develop a more detailed understanding of decision criteria, decision-making processes, organizational cultures, formal and informal communication structures, multiagency response mechanisms, and associated strategic issues. From a pedagogical perspective, exercises address adult learners' preference for active and experience-centered learning and opportunities for more inductive or guided-discovery learning approaches with flexibility for the incorporation of error-based learning that must be otherwise avoided in real crisis events. Training for crisis is unique in its need to simulate high levels of nonroutine, uncertain, and complex problem solving needing urgent action and intricate patterns of intra- and interagency decision making and communications.

Decision makers normally have two types of responsibilities: routine and nonroutine matters. During a normal situation, the exercise participants carry out their routine daily tasks; however, it is during abnormal situations that they will be expected to confront challenges problematically. During unexpected emergency events or abnormal situations, decision makers will be expected to confront many challenges, including (1) ill-structured problems; (2) uncertain dynamic environments; (3) shifting, ill-defined, or competing goals; (4) action/feedback loops; (5) time stress; (6) high stakes; (7) multiple players; and (8) organizational goals and norms. These problems prevent decision makers from communicating and disseminating decisions, and they create difficulties coordinating with other agencies. They require flexible, adaptive, and effective individuals and teams with the appropriate skills and attributes in order to provide a timely and coordinated response and to manage the wider impacts of the emergency. As a consequence, exercises normally focus on the development of these nonroutine skills.

Trend of Modern Crisis Exercises

As a result of the increasing frequency and magnitude of natural and human-made disasters, there has been increasing demand for modern large-scale crisis exercises to be held, aiming to train for multiagency communication and coordination skills. These exercises have three distinct characteristics: the involvement of more participants, blurred objectives, and vague ownership.

First, these large-scale exercises normally involve large numbers of participants. These participants are also normally drawn from different agencies and organizations. In the European Union (EU), there is a trend to conduct cross-boundary exercises where participants from several states are involved. For example, in 2008, Hungary hosted a cross-border emergency response exercise that included nine EU countries plus Croatia (EU-HUROMEX 2008) and highlighted the importance of communication and coordination between nations.

Second, because these participants are from different agencies, organizations and states, they each have their own exercise control posts or control and command centers. For example, the scenario of Flood Ex was set to be the equivalent of the

1953 tidal flood in the UK and the Netherlands. The exercise included field and control post simulations. The field exercise took place in several locations in Amstelmeer, the northern part of North Holland, while the control post exercise was based in the participants' crisis centers. The limitation of exercises of this type is that normally participants from different control posts are not able to meet each other during the exercise. This reduces the nature and complexity of a disastrous event, which is the key to training individual responses.

Third, as the exercise becomes so extensive, the ownership becomes vague. It is easy for a modern large-scale exercise to attract many relevant agencies to engage with, from local to national levels, and such an exercise could easily involve hundreds of participants. For example, the UK national flood exercise Triton 2004 involved about 1,000 participants from more than 60 different organizations, and more than 10,000 people took part in the exercise Watermark 2011. Although each participant unit/organization was provided with a generic scenario, they could create their objectives depending on their needs. What made the ownership become vague was that most of the agencies participated in the exercise at the last minute; each control post designed its own injects and conducted different types of exercises in accordance with its perceived requirements.

The Challenges of Crisis Exercises

It is widely recognized that the challenges of emergency response exercises include limited training time available and inadequate funds. They also require large numbers of personnel, for example, exercise planners, participants, observers, and training technologists. As a result, it is difficult to conduct frequent exercises. From a pedagogical perspective, several challenges when arranging crisis exercises can be summarized, including (1) fidelity and realism, (2) evaluation, (3) retention issues, (4) generalization issues, (5) progressive training, and (6) increasing flexibility.

Fidelity and Realism

Fidelity refers to the degree to which the scenario of the exercise represents the reality; in other words, it is the realism of the scenario. Fidelity examines the contents, processes, and context of an exercise. Content fidelity considers the degree to which the materials used in an exercise are equivalent to the reality. Process fidelity refers to the degree to which the operations and interactions correspond to real-world situations. Context fidelity indicates the degree to which the simulated scenario is similar to the reality.

There are controversies as to how much reality should be represented in an exercise to facilitate learning outcomes. Traditionally, it is believed that the higher the reality an exercise presents, the higher the learning that occurs. It is also argued that high psychological fidelity could increase learning outcomes, if it is not possible to establish context fidelity. However, recent scholars believe that a real-world scenario is not necessary for learning, as higher fidelity might reduce the skill acquisition for participants, in particular for those beginners in crisis response skills. Higher reality can be dangerous and stressful, and learners might be overstimulated. Consequently, it is suggested that low-fidelity exercises could facilitate learning nontechnical skills.

Evaluation

Because one of the challenges of current crisis exercises is to set up clear objectives, especially in strategic exercises where more abstract and complex tasks are involved, it is difficult to determine the internal validity—in other words, learning the outcomes or evaluation criteria—of an exercise. First, the roles and responsibilities of the organization involved in responding to a disaster could be varied because of the nature of the crisis; consequently, the missions and tasks that are assigned to an organization would be different. Second, crises are low-probability events and do not occur sufficiently frequently to generalize a set of measurements to evaluate the effectiveness of the practice. Lastly, although there are sets of evaluation methods for operational levels, it is difficult to determine the measurement of skills required at the strategic levels, such as coordination and communication.

Retention and Generalization Issues

To retain the knowledge and skills gained in an exercise until the next training or crisis occurs is another challenge. Because full-scale exercises are very expensive and involve many personnel, they do not happen frequently. Because the probability of a major incident taking place is comparatively low, not all skills learned in a training exercise session are likely to be used straightaway—some of them may never be needed.

The fourth challenge is to apply what has been learned from a scenario to different types of incidents or disasters. Exercises in emergency services are normally scenario based. However, these scenarios do not necessarily reflect what is happening in real life. How the individual generalizes the skills learned in the exercise and applies them to different scenarios and real-life situations is also a major challenge.

J. K. Ford and A. M. Schmidt propose that guided discovery learning, error-based learning, and metacognitive instruction can help build those adaptive capabilities that are required in an emergency response. Their proposal stresses the importance and usefulness of individual learning, but it ignores the element of multiagency coordination and communication.

Progressive Training

A training program for an individual should be planned and should be progressive. Professional experts normally use their existing knowledge to understand new skills. Based on this knowledge, they are expected to learn from simple to complex skills through a series of exercises. If exercises do not have a consistent training method or format, they do not have the characteristics for gradual progression.

Flexible Delivery Strategy

W. G. Green suggests that alternatives should be provided to increase flexibility in delivery strategies. First, he recommends that training taking place in an office environment or at home should be taken into consideration; hence, the use of the Internet can be a good option. Second, self-directed learning should be added onto exercises. Third, exercises should be conducted both by fixed schedule and for individuals to participate in their own time. By allowing participants to control their own learning, the skills gained from the exercises will last longer.

The Use of Virtual Worlds

Researchers have attempted to use different technological tools and applications to avoid the limitations of traditional crisis exercises and to increase the efficacy of learning activities while improving learning outcomes. These tools can be categorized as nonimmersive or immersive in character. Nonimmersive tools, for example, may include text-based Web tools, which create a simulated environment for participants to act in a safe and controlled scenario. Other tools include the use of computer modeling, interactive Web sites, and online discussion rooms to support decision making. These provide players with a real-time-based environment. Although this may not be as immersive as in 3D modeling of an environment, it can nonetheless allow players to exchange their feedback and reflections. In contrast, immersive computer-based simulations could represent complex workplace dynamics. They also represent the complex psychological, social, and political factors in the multiple-agency communication and coordination areas. In order to evaluate the players' performance, strictly controlled environments are normally used in these computer-based training exercises, which might limit the degree to which true fidelity can be demonstrated in the simulations.

More recently, new virtual world and games technologies allow for greater immersion within 3D environments via avatars that represent the individual in the 3D environment. This is opening up the potential for training exercises and scenarios that can be enacted with distributed learner groups, with scope for more dynamic scenario editing and therefore greater potential for creating dynamic and interactive virtual exercises.

Failed States

The identification of a nation as a failed state centers on that state's inability to provide citizens with a safe and effective environment as well as its inability to operate within the international community. Social, economic, and political factors shape the determination of a nation as a failed state. Failed states are also generally unable to provide effective internal crisis management and often are the recipients of international crisis management as well as economic development aid. International aid that operates in support of a failed state's central government helps strengthen internal crisis management development as well as economic, political, and social development in both the short and long terms.

Although the term *failed state* has no mutually agreed upon definition, the definition developed by the think tank Fund for Peace is the most widely accepted among the international community. Since 2005, the Fund for Peace has coordinated with the magazine *Foreign Policy* to publish an annual Failed States Index, ranking the world's failed and vulnerable states based on its calculation of social, economic, and political criteria. Critics of the generally accepted categorization of failed states argue that its basis lies in a failed state's comparison to mostly Western developed countries as well as the label's negative connotations.

Failed States and Crisis Management

A combination of factors rather than a single factor leads to the determination of whether a nation is considered a failed state. These factors are based on analysis of either a state's resources or the functionality of its central government and associated state institutions. The factors considered as components of a failed state are often either conditions that can lead to crisis or crisis conditions in themselves. There is also a strong correlation between the factors that cause states to fail and the factors that lead to poor crisis management planning and response, leaving citizens of failed states vulnerable to crises and their short- and long-term impacts.

Social factors commonly found in failed states include demographic pressures such as high population densities, a lack of sufficient resources to provide for the population, and widespread or long-standing conflicts among ethnic, religious, or other groups. Social injustice or repression is also commonly present. Results can include high crime rates, high infant mortality rates, reduced educational access and attainment, poor health care, and reduced life spans. Long-term human flight and notable expatriate communities may result as those with the means to immigrate leave the country for better opportunities elsewhere. Those left behind are rendered more vulnerable to crisis.

Economic conditions commonly found in failed states are characterized by uneven economic development resulting in large gaps between economic, racial, or ethnic groups in areas such as employment and class status. Steep sudden or long-term economic decline may precipitate economic crises that further weaken central government, or the central government may be plagued by corruption fueled by resource abundance. Black markets or hidden economies based on illegal activities such as drug or diamond smuggling, human trafficking, or counterfeit goods may thrive. The economy is also particularly vulnerable to global economic crises.

Common political characteristics of failed states include lack of legitimate government, ineffective state institutions, lack of government transparency or accountability, widespread government corruption, and lack of or severely limited national participation within the international community. Symptoms of political dysfunction are unwieldy government bureaucracy; lack of or uneven legal enforcement; widespread loss of public confidence in government; loss of territorial control; military intervention within the political arena; widespread human and other rights violations; the institutionalized disenfranchisement of racial, ethnic, religious, or other groups; the distribution of political benefits to the elite; and lack of or poor public services.

The social, economic, and political characteristics of failed states often create or exacerbate crisis situations and increase the vulnerability of their populations to crisis impacts from natural or technological disasters, environmental hazards, or conflicts. The formation of large populations of refugees and displaced people, refugee camps with untenable living conditions, conflicts over scarce or unequally allocated resources or infrastructure, famine, disease pandemics, international or national border and land ownership conflicts, and genocide are crises commonly engendered within failed states.

The characteristics of failed states also contribute significantly to these states' inability to effectively develop crisis management plans and to effectively respond to the crises themselves through the relief, recovery, and rebuilding phases. Failed states are often unable to provide effective strategic crisis management planning or response, resulting in the involvement of the international aid community.

International Aid

Failed states are often the targets of international concern and aid mobilization, with an emphasis on the alleviation of poverty and other sources of distress, restoration of sustainable order and peace, and economic revival or development. The international community also becomes involved because of the potential international repercussions of crises within failed states. A lack of clear, centralized objectives and strategies; a lack of effective aid allocation; and neglect of the need to construct and actively involve state and local government organizations can plague international crisis aid.

Effectively rebuilding failed states and managing crises within them requires long-term international assistance in terms of both resources and personnel. Traditionally, more long-term international development aid has been directed toward developing nations with stronger central governments that will effectively manage such aid and help ensure that it reaches its intended target populations. Failed states have historically received more short-term aid in response to highly publicized large-scale crises such as terrorist attacks, refugee crises, massacres, or natural disasters. This aid then drops off precipitously once the immediate crisis has passed from the news.

Leading international agencies involved in crisis management include the United Nations, the World Bank, and the International Red Cross. A variety of local, national, and international government agencies and nongovernmental organizations (NGOs) are also involved. The United Nations Millennium Development Goals and the Paris 2005 and Accra 2008 conferences are key international agreements pertaining to international aid effectiveness. Poverty reduction and economic development are the centerpieces of these agreements. Common forms of international crisis management aid are the cancellation of outstanding national debts; the provision of emergency relief supplies, personnel, or technical equipment; and crisis management planning and recovery assistance.

Lack of an effective central government and the presence of multiple crisis relief and recovery organizations often results in numerous difficulties that plague international aid management. The absence of centralized management oversight, effective leadership, or intergovernmental or agency coordination, coupled with the presence of multiple administrations, is one of the most critical of these problems. The international aid community lacks a single administration responsible for establishing central objectives and coordinating and providing oversight for aid efforts. International crisis management efforts can also be hampered by inadequate training or shortages of qualified personnel, high turnover rates, lack of sufficient local knowledge, environmental safety or personal security issues, and waning long-term commitment of donors and resources.

Often, aid organizations establish their own political administrations that operate in addition to existing or developing state institutions. A provisional administration sanctioned by the United Nations or other international relief agency may also be present. When international aid organizations operate independently from, rather than in support of, state administrations, those state administrations can be further weakened and less able to respond effectively to present and future crises. New state governments determined by internationally observed democratic general elections do not always result in the effective state government control and resolution of conflict needed for effective crisis management. Local militias, mafias, guerrilla movements, or other armed groups often arise in the face of a weak or failed central government. Unequal and inconsistent resource allocation, poorly managed and inconsistent relief efforts, and relief and recovery efforts that do not align with the most urgent national needs can also result, especially within the short term.

One of the first goals is the assurance of the safety of the failed state's population. Although the intervention of foreign forces often provides short-term governmental agency and security forces, the development of effective long-term local and state government mechanisms and national security forces is vital for long-term security. A failure to develop local institutional capacities can threaten long-term future stability and sustainability. Long-term state governance and national security will aid the development of future local- and state-level crisis management planning as well as crisis mitigation and response.

Failover

During times of a realized crisis, business operations may find themselves in a position where they must execute a failover scenario. At that time, a failover can occur from a technical standpoint, meaning systems, certain servers, or complete data centers need to move to a secondary or backup setup, or from a geographical and/or personnel standpoint, meaning operations must be moved to an alternate local or international location, depending on the circumstances of the crisis, availability of critical operations personnel, and its level of severity. Many business leaders today view failover plans as a critical component for the future viability of a business not only to continue key operations but also to sustain themselves after the incident is over and the recovery stage begins. It is unfortunate that many businesses have ceased to exist for no other reason than they did not form robust failover plans for their information technology (IT) infrastructure, nor for their personnel and physical locations, and a real crisis did come their way with no way to recover from it.

Failover From a Technical Perspective

For many businesses and government agencies today, a complete system failure is considered a high-impact disaster, so IT departments or contracted partners are turning to solid preparations and updated technology to ensure that during times of crisis, systems appear to continue to be operational, even if there are immediate failures in a data center environment.

Traditionally, a computer server breakdown used to mean widespread panic and a scramble to find backup tapes and a spare server to restore information. Inevitably, this meant the operations of the business would be interrupted, people would become frustrated over not having access, and even a loss of data could occur. Recovering from a backup could take hours; even planned maintenance can take the server down during business hours, leaving teams unable to work. But with more advanced technology available, moving from one system to another has become reasonably automatic, and in cases where an entire data center failure occurs, a redundant data center is ready to ensure that interruptions are very minimal in nature or not even detectable to the average system user at an organization.

Some ways of providing technical failover are either with a fault-tolerant machine with duplicate hardware or with a high-availability (HA) architecture. The duplicate hardware in a redundant architecture works as a "copy" of the main system, so in the event that the main system does fail, the redundant machine takes over and becomes primary until repairs are made to the primary server. Some larger corporations, or ones that host extremely sensitive data, have sought additional layers of security and assurance that a system failure will not stop operational capability, and this is where the HA architecture comes into play. HA works by linking several machines together so that the failure of one computer brings another online—the users see no difference. The applications run on the servers, but the data are stored on the network, thus adding more protection to the environment. When any single server fails, users are redirected to other servers while the failed server is repaired or replaced and brought back online. In any event, a technical failover, from single system failure to complete data center shutdowns, can take place with minimal impact.

Physical Site Failover and Personnel Elements

The most common viewpoint of a failover is from a technical perspective, with servers, networks, phone systems, and data centers. But there are additional nontechnical elements in regard to the availability of a physical site or workplace, as well as in the event of suddenly having a severely reduced staff, or no staff at all, to continue operational capability at that workplace. Site and personnel failover strategies and responses come in many shapes and forms, and they all depend on whether the crisis is isolated to a single site or multiple sites in a campus environment, or if the crisis is a regional one widespread across an area that affects multiple businesses and/or government operations, and also reverberates a negative effect on personal life safety at home.

Site failover can consist of several options, with plans in place for an alternate worksite location(s) so that the operation has a single or multiple set of locations that meet the requirements to continue working in the event that the main location is no longer accessible. Other site failover strategies can include a mobile worksite, which is a specialized set of custom-designed mobile trailers equipped with all of the necessary infrastructure, such as workstations, kitchen facilities, restrooms, printers, faxes, Internet access, and other office-related supplies. In all cases, certain considerations must be made with respect to physical security mechanisms, heating and cooling, adequate power supply, personal needs of the staff, and access to pertinent information and documents.

Sometimes a regional disaster, such as a flood, hurricane, pandemic, or earthquake, can affect an area to the point where alternate work locations are not a viable solution, and the staff is affected in a way that they are not available to report for work. In this instance, a site and personnel failover can take place. Some companies and government agencies have available secondary workforce capabilities located in different regions nationally, or internationally, where a trained workforce can address critical-only functions as additional workload until such time when the regular workforce can return and the functions can then be failed back. This takes careful planning to ensure proper system access, function knowledge via cross-training of personnel, and identifying which functions are critical and must continue.

Failover Activation Considerations

As plans are put in place to have a significantly strong failover capability, one must consider how to activate that capability, at what level it is to be activated and the overall process of invoking a failover strategy. There is a very fine line that must be drawn with respect to the timing of invoking a failover at the right time, or there could be impacts to the business or government operation if the failover is invoked too slowly or beyond its proper threshold. A premature activation of a site or personnel failover can be very costly, bring confusion and potential panic internally, create undue media exposure, and affect overall reputation and professionalism as viewed by the public eye.

Technical failover, on the other hand, is a fairly black-and-white scenario, especially since modern technology causes a server failover to invoke the process to the available other servers automatically and notifies IT teams via system messaging or network device monitoring alarms. But when a complete data center needs to fail over to a secondary, backup, or disaster recovery center, this does require careful planning and execution to ensure minimal data loss and downtime, and that the secondary data center has all capabilities up and running in a timely manner. IT departments today dedicate a tremendous amount of time to this area, and most exercise their capability on an annual basis to ensure staff and capability readiness.

From a cost perspective, site and personnel failovers are expensive in nature, mostly due to the cost of logistics that stem from moving a complete business or government operation from one facility to another in a very short period of time, sometimes as quickly as within a single business day, depending on how critical the functions are to the public or the overall financial impact of having the business operation halted for a period of time. Investments today in the overall planning, available physical site and technical infrastructure, cross-training of personnel, and testing of all capabilities range broadly in the private business and government sectors, with careful considerations made to balance the efforts and costs of readiness.

Plans for Strengthening Business Resiliency

There is much discussion today in regard to failover and how that relates to a more resilient business or government operation. Failover, though one of many aspects of overall resiliency, is considered a key element in the assurance that a business or government agency can continue functioning during and after a crisis, and many business continuity and emergency managers are striving to integrate failover processes into the overall readiness strategy as one of their main goals.

To accomplish this goal, many companies and government agencies are developing all-encompassing, cross-functional programs to maintain continuous business operations and access to critical business data, while managing and predicting costs to achieve and maintain a highly ready state. The ability to blend solutions to accommodate the most critical business processes and applications during a failover scenario is a trademark of a resilient company.

Because business strategy is the formed roadmap for achieving its goals, failover strategy must also be integrated into the overall business culture to ensure that it works in harmony with the goals of the business and not be intrusive, but rather be viewed as productive. One of the main targets of failover planning is that it is such a strong part of overall preparedness that the actions within it are systematic, rather than impulsive or even frantic. As with any strategy, it must be under a form of governance to be monitored, enforced, and reviewed on a regular basis.

Three best practice points will differentiate a good failover plan to a resilient culture-driven operation: exercise and test, awareness and education, and communications. All technical and business mitigation solutions must be validated and tested. Exercise strategy helps protect the organization's investment because without periodic exercising, the effectiveness of the plan can quickly erode. Plans should be exercised regularly, commensurate with their importance to the company, and at least annually. Different types of exercises can be employed to ensure all facets of the plan and the solution are validated with respect to system and site failover. These can include tabletop or walk-through discussions for plan execution, or simulation through active participation to enable the process or technology external to the production environment, including full failover by switching from the production environment and operating from an alternate site.

Education and training of personnel in special, critical, and multiple roles plays a significant part in the success of the failover plan execution and may influence the time required to execute tasks. An awareness and education strategy helps ensure all employees are aware of the plan in general, not just those who participate in a failover regularly. Pandemic preparedness is a good example of using awareness programs to educate personnel on simple techniques to maintain their health and the health of their family members to mitigate the risk of high employee absenteeism predicted during a major flu outbreak, which would invoke the personnel failover plan.

Communicating during a crisis is probably the single most import aspect of a failover strategy. The key is maintaining current, accurate communication lists for both internal and external contacts, written scripts for internal and external communications, and company fact sheets, and ensuring employees are versed in public relations, legal response, and insurance. The communication plan should include contingencies for the loss or major degradation of standard access for both voice and data networks to ensure that messages are being received during a failover situation. Reliance on the Internet and intranets can be affected, so contingencies that include out-of-region service providers still prevail in some cases.

Having failover plans in place, exercising and testing them, and overall readiness through education and communication contribute greatly to the overall resilience strategy and can bring a sense of comfort, assurance, and strength in times of crisis.

Famine

Crisis management of famine is best understood within a wider context than merely focusing on the final event called “famine.” An appreciation of this subject also requires some insight into decision-making processes and structures and interactions within a particular context such as region, nation, or locality. Indeed, studies have indicated that famine is often a product of multiple failures at various levels of governance or society. Indeed, doing justice to this discussion requires an exploration of a series of issues that lead to the point in time when catastrophic events descend into a crisis.

Are Famine Crises Unavoidable?

A large body of evidence has indicated that famine as a crisis principally results from poor policy, decision making, and planning. Interestingly, when famine strikes a region, the media portrayal of the crisis tends to be strikingly dramatic, as though the causes of a famine are entirely unforeseen. Because appeals for donations tend to be extremely urgent and often accompanied by heightened sensitivities, any appearance of critical and sometimes perfectly rational voices probing

In July 2011, 40-year-old Halima Bare attempts to find shade in Elado village in the Wajir District of northern Kenya, one of the regions hardest hit by ongoing drought. Halima walked 31 miles with her seven children to Elado after the drought killed most of their livestock. In Elado, they have one meal a day, which she shares with her children, taking the remnants. By July, 12 million people in east Africa—Somalia, Ethiopia, and Kenya—were struggling to find food or drink following the worst drought in 60 years.

questions into causation of the crisis are often silenced and dismissed. Yet there are facts about famine and crisis management that have been learned through history, research, and experience that justify such critical perspectives and can offer valuable reflection and lessons for the future.

Preparedness is an important aspect to effective crisis management in regard to famine. In the aftermath of satellite technologies and indeed following, for example, Landsat missions since the 1970s and others like them, there have been advances in the understanding of drought, for example, and famine in general. There has also been a marked increase in the type and quality of information and historical data that can be utilized as a baseline for planning within the management of crisis systems. Unfortunately, such invaluable information seems not to have been sufficiently utilized and harnessed for national strategic crisis and emergency management planning. Opportunities brought about by technological advances have, in a significant number of cases in the developing world, not been matched with corresponding national crisis management strategies and mechanisms. A good example to illustrate this lack of preparedness can be found in, for example, the case of Ethiopia where, despite the availability of historical crisis data and a pattern of recurring famines, the country is chronically underprepared for famine crisis management. Yet Ethiopia has, over at least two millennia, gathered a wealth of information relating to famine crisis. The story and history of Ethiopia is punctuated with droughts and famines. Thus, it would seem perfectly plausible to suggest that against this history, both locals and the government in Ethiopia would be familiar with the risks and vulnerabilities facing them. Indeed, during the intervening time between the 16th and the 20th centuries, two notorious famines or droughts struck Ethiopia, leading to the coining of the words *kifuken* and *kwachine* and these words being added to the Ethiopian vocabulary. The use of the two words conveys within the Ethiopian tradition a sense of extreme notoriety of the crisis.

Studies of droughts and famine crises have led to espousing particular approaches to farming and subsistence agriculture, in particular. Sporadic efforts by nongovernmental organizations (NGOs) and agencies have led to institutional learning whereby some farming practices are being advocated over others as alternatives for traditional ones. In parts of Ethiopia, for example, some subsistence farmers have traditionally kept large farm animals such as cattle. But as crisis becomes a recurrent event, there is a growing acceptance that land carrying capacity (the extent to which land can be exploited without adversely affecting it) for large animals is under extreme pressure during droughts, so new practices are emerging. Faced with dwindling animal feeds during droughts, subsistence farmers rearing shoats (smaller farm animals) will need comparatively smaller amounts of feed to manage than they would for larger animals.

Training as a Crisis Management Strategy

Training and resource development is another important aspect for managing a famine crisis. Understanding crisis alone is insufficient unless the right resources are made available at strategic, operational, and community levels to minimize the worst excesses of a crisis. Effective management for famine must entail engaging in a continual process of scanning the "horizon of the crisis-prone regions" and developing the knowledge and skills for dealing with potential and prevalent risks. Crisis in the context of famine is perhaps analogous to signs and symptoms of an underlying illness that too often only a trained crisis management team and community can assess, then take timely remedial action. Locals, particularly in famine crisis–prone areas, will normally or traditionally have some form of crisis coping mechanisms and strategies. However, when these traditional strategies and coping mechanisms are strained to their limit, they will show signs of tear and wear and general collapse by being ineffective in serving the people. A trained crisis manager, management team, government authority, and community can in many cases identify a point where the strain between traditional coping mechanisms gives way to famine. Prior to famine taking a foothold, affected people will go through stages of utilizing a range of personal resources they might have, including utilizing their social networks, selling some animals, selling nonessential items, and, in the later stages of the crisis selling essential items. When personal alternatives and resources are exhausted and possible safety nets are not readily available, the migration to seek other sources of livelihood, in urban areas for example, begins. Before this time, effective and trained crisis teams should have acted at multiple levels, supported by existing crisis management plans, monitoring of markets, coherent transport and health infrastructure, and the necessary technical know-how to monitor and evaluate the prevailing situation before it develops into an emergency.

Decision Making, Policy, and Famine

Poorly configured crisis management mechanisms—or lack of them—can adversely contribute toward the escalation of a famine crisis. Between 1845 and 1851, one of the worst famines in the history of Ireland claimed the lives of approximately 1.5 million people. The escalation of this crisis and subsequent famine has been attributed to the British colonial powers and indifference in designing effective and timely crisis plans and actions for dealing with the situation. Potato blight affected yields, which dwindled for three consecutive years in Ireland. Famine followed, and lack of food meant that people were extremely weak and unable to even accept some jobs that were eventually offered as alternative sources of livelihood for famine-affected people. Nearly a hundred years later, a similar situation repeated itself in Bangladesh in 1943. The Gulf of Bengal had been known as "the rice bowl of India." During the period of World War II, a severe cyclone hit the country at a time when farming activities in the country had been severely affected by the war. Instead of managing the crisis effectively, Britain continued to export food out of Bengal, just as had it been done about 100 years earlier in Ireland. Of course, in the case of Bengal it must be stated that the coincidence of events, the cyclone, and World War II contributed to the poor crisis management.

Global Institutions

In addition to the above, global institutions occupy a very critical role where their influence and efforts are appropriately channeled. It cannot be disputed, for instance, how the efforts of organizations such as the Food and Agricultural Organization (FAO) and the World Food Programme can help mitigate and respond to crisis. Similarly, economic institutions such as the World Bank and the International Monetary Fund (IMF) can make a positive contribution. However, in certain cases some critics have argued that some decisions by global institutions have proven ineffective in crisis management. In 2002, for example, Malawi (one of the poorest countries in the world) experienced one of the most critical food crises that the country had ever faced. The World Food Programme was extremely effective in responding to the crisis. However, the case of the Malawi famine raises many issues for crisis management. Despite sporadic food shortages, recent history indicates that Malawi had largely averted extreme food shortages and was relatively food sufficient. Prior to 2002, and apart from the famine of 1949, Malawi had not seriously faced extreme food shortages. Since gaining independence from Britain in 1964, the country continued on its course to strengthen its focus on food security. This commitment to agriculture and food security was underlined by the importance and high standing attributed to the Ministry of Agriculture within the Malawi government cabinet. Despite Malawi's imbalanced acreage of land allocated to tobacco farming over food crops, there was sufficient evidence to underline Malawi's commitment to food security and self-sufficiency. Food security approaches were actively pursued by the Malawi government prior to the food shortages of 2002, and this strategy also included providing government subsidies to subsistence farmers for agricultural inputs.

In further strengthening its food security, a few years earlier the government of Malawi had also built grain banks (reserves) and stocked them to act as a safety net in the event of severe food crisis. Indeed, the Agricultural Development and Marketing Corporation (ADMARC), a Malawi government institution, had historically played a key role in buying excess grain harvest from local people, who are mostly subsistence farmers, and selling it back to the people at affordable prices when food was scarce. Although the food crisis was aggravated in part by flooding that was immediately followed by drought, the IMF and World Bank have been widely criticized through claims that the institutions exerted pressure on the Malawi government in relation to the Structural Adjustment Programme (SAP) debt repayments and liberalization and the government use of food reserves. This significantly contributed to the food shortages in Malawi in 2002. It would seem that the famine in Malawi could have been averted by informed decision-making-founded research both vertically and horizontally, understanding thoroughly the relationships between different structures and processes. Knowledge and information gaps and communication inefficiencies at both international and national levels and inability to build capacities and robust crisis management structures and governance can render a crisis unmanageable.

Perhaps most important, national institutions need to be confident of support from vertical powers by international institutions in appreciation of national contexts and the help required by states to have effective crisis management plans, robust communication processes, and information systems that are managed by trained staff and volunteers.

Federal Bureau of Investigation (FBI)

The Federal Bureau of Investigation (FBI) is one of the main actors that respond to crisis situations in the United States. Hence, it is important to know its organization, mission, tasks, and operations. The FBI is a federal law enforcement agency. It is one of many federal organizations tasked with law enforcement. The FBI was founded as the Bureau of Investigation in 1908 by executive order of President Theodore Roosevelt. Its name was changed in 1935. The head of the FBI is the director, who is appointed by the president and confirmed by the Senate. The FBI director is appointed for a maximum of 10 years and answers to the attorney general. Congress oversees the FBI's budget appropriations, programs, and chosen investigations. The director of national intelligence oversees the FBI's intelligence activities.

The FBI headquarters is in Washington, D.C. The FBI has 56 field offices that are located in major cities of the United States. Furthermore, the FBI has smaller FBI field agencies in various cities and towns nationwide. The smaller FBI field agencies are called resident agencies, and there are roughly 380 resident agencies in the country. Moreover, FBI international offices exist in U.S. embassies throughout the world. The FBI international offices are called legal attachés, and there are more than 60 legal attachés (liaison offices) in the world.

Special agents for the FBI are trained at the FBI Academy in Quantico, Virginia, for 20 weeks. The FBI had a total of 35,664 personnel as of February 2012. Although 13,778 of them were special agents, 21,886 of them were support personnel (professional staff), such as intelligence analysts, scientists, information technology specialists, language specialists, and other professional support personnel. The FBI special agents make arrests, carry firearms, and serve warrants.

Investigation and Intelligence

The agency is an operational (mainly investigation) enforcement agency as well as an intelligence agency. The FBI has two primary missions: investigation and intelligence. Its particular mission is to fight against terrorism and foreign intelligence. The FBI collects, shares, and analyzes intelligence to back its own and also its partners' investigations.

The FBI investigates and prevents international and domestic terrorist activities. The FBI is the lead federal law enforcement organization to investigate cases relevant to weapons of mass destruction, including nuclear weapons and radiological, chemical, or biological agents. Crisis managers outside law enforcement may request the assistance of the FBI. For example, the FBI Weapons of Mass Destruction Countermeasures Unit (WMDCU) has exercises on weapons of mass destruction (WMD). Those exercises meet the specific needs of crisis managers, who may ask for the assistance of the FBI on WMD. In addition, the FBI Crisis Management Unit (CMU) provides comprehensive crisis management training to federal, state, and local agencies. The CMU also conducts research in the field of crisis management, particularly information techniques and new crisis management procedures.

Terrorism-related incidents such as money laundering, violence at airports, and assaults against U.S. officials are also investigated by the FBI. Although bombing incidents are under the jurisdiction of the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF), the FBI conducts collaborative investigations with the ATF. In drug trafficking incidents, the FBI conducts investigations together with the Drug Enforcement Administration (DEA). While prosecuting drug trafficking cases, the assets of the criminal enterprise are seized in order to eradicate the whole criminal organization.

Private sectors help facilitate the FBI's work in tracking down terrorists and criminal and the

FBI works with private-sector organizations to prevent physical and electronic attacks and intrusions. The Domestic Security Alliance Council (DSAC) was created as a partnership between the private sector and the FBI to enhance the effectiveness of information exchange. InfraGard, another partnership in which private organizations share intelligence and information such as expertise and strategies with the FBI, has more than 30,000 members from the private sector. FBI agents who work for the InfraGard program contribute invaluable information and news such as case studies, threat alerts and warnings, overall threat assessments, and vulnerabilities.

Federal law authorizes the FBI to investigate all federal crimes that are not in the investigative jurisdiction of another federal law enforcement agency. The FBI investigates major and complex criminal incidents that any local and state law enforcement agency may not deal with alone. The FBI investigates major crimes such as cyber crime, public corruption, violations of civil rights (such as hate crimes or human trafficking), organized crime, white-collar crime, violent crimes (such as bank robbery, art theft, and crimes against children), and major thefts. Two hundred violation categories of federal law allocate a duty to the FBI to investigate the criminal cases.

The FBI assists federal, state, local, and international law enforcement agencies. For instance, the FBI supports other law enforcement organizations by providing various services such as laboratory examinations, fingerprint identification, and police training. Scientific examinations of evidence are conducted by the FBI laboratory for all federal, state, and local law enforcement agencies in the United States at no cost. The FBI shares identification and criminal history information with federal, state, and local law enforcement organizations. If a person is wanted by a local police department for committing a crime, the wanted person's name and identifying information are also entered into the computerized database (National Crime Information Center), which is accessible to all law enforcement organizations throughout the United States; his or her fugitive status will be seen by any law enforcement agency during an inquiry. The FBI trains some qualified officers from state and local law enforcement agencies. The FBI National Academy provides training to mid-level international, local, and state police officers. It is believed that this training program increases cooperation between local law enforcement agencies and the FBI. The FBI special agents sometimes work together with officers of state, local, and other law enforcement agencies on task forces created to fight terrorism, narcotics, organized crime, gangs, kidnapping, bank robberies, and motor vehicle theft.

The agency also works through federal prosecutors. FBI special agents take an individual arrested by the FBI into custody until the first court appearance. The arrestee is photographed and fingerprinted, and his/her voluntary statement is taken while in custody. The FBI takes intelligence on a confidential basis from the informants who are not FBI employees. Informants may be paid compensation.

The FBI Critical Incident Response Group (CIRG) gives prompt expert assistance to cases in a crisis, such as crisis management, the abduction or mysterious disappearance of children, hostage negotiation, special weapons and tactics, and criminal investigative analysis. The CIRG also supports FBI undercover personnel's appraisal, selection, and training processes.

The FBI keeps statistics on criminal incidents committed in the United States. The Uniform Crime Reporting (UCR) program was created by the FBI to collect information on crimes reported to law enforcement organizations. The main crime categories are forcible rape, murder, robbery, burglary, aggravated assault, arson, larceny-theft, motor vehicle theft, and hate crimes.

Federal Emergency Management Agency (FEMA)

The Federal Emergency Management Agency (FEMA) is an agency of the U.S. government responsible for disaster mitigation, preparedness, relief, and recovery. FEMA describes its role as consisting of a variety of different components: providing service to disaster victims, integrated preparedness, operational planning and preparedness, incident management, disaster logistics, hazard mitigation, emergency communications, public disaster communications, and continuity programs. An independent agency beginning in 1979, FEMA became part of the then newly formed Department of Homeland Security (DHS) in 2003. Several documents and pieces of legislation cover how FEMA is organized and operates, including the Robert T. Stafford Disaster Relief and Emergency Assistance Act (Stafford Act, an amendment to the Disaster Relief Act of 1974), the Homeland Security Act of 2002, and the Post-Katrina Emergency Management Reform Act (PKEMRA or the Post-Katrina Act).

FEMA follows an all-hazards approach, focusing on preparedness and response to all types of hazards, including natural, human-made, and attack. Natural hazards are naturally occurring events, such as tornadoes, that may threaten a population. Human-made hazards are events like chemical or oil spills. Attack hazards include events such as terrorist attacks. FEMA is organized to respond to any of these types of disasters at any time. Efforts to mitigate, prepare for, or respond to each of these types of disasters can often be used during other types of disasters. For example, communications equipment used in relief efforts for a major flood can and should also be used in responses to a domestic terrorist attack. Although the specific issues that need to be address in preparedness or response to different disasters may vary, basic needs and approaches like good communication are universal and should be applied to all disaster responses.

Although the term *FEMA* is generally used to refer to federal-level government response, the agency is also organized to account for and assist with preparedness and response efforts at the state, tribal, and local levels. Through FEMA's encouragement, training, and planning for communication and cooperation across agencies in these different levels of government, as well as among nongovernmental and private organizations, crisis managers are ready to offer assistance to other areas as needed and to accept help when their own areas are affected by disasters of any type.

Four Stages of Disaster

Disasters have four phases in FEMA's approach: mitigation, preparedness, response, and recovery. Mitigation efforts are those steps taken to reduce the effects a disaster will have on an area or the likelihood that a hazard will ever hit an area at all, for example, the construction of levees to reduce the chance of a flood affecting an area or to reduce the amount of water that would enter a space during a flood. Preparedness efforts are those efforts made to actively prepare for an upcoming disaster, for example, predicting a hazard and where it will strike, issuing evacuation orders, and opening shelters. Response efforts occur during and just after a disaster, for example, emergency rescues and the distribution of food and water. Finally, recovery efforts are long-term efforts to rebuild after a disaster in an attempt to return things to as normal a situation as possible, for example, the reconstruction of schools and businesses or the repaving of damaged roads. All of these are steps that crisis managers should be involved in, according to FEMA's own literature and training manuals.

FEMA relies on response at different levels of government. Residents of the impacted area are their own first line of responders, and FEMA's organization begins with the idea that these individuals and families have a certain amount of basic

Case Study: FEMA and Crisis Management in Hurricane Katrina

Focusing specifically on the Federal Emergency Management Agency's (FEMA) role in crisis management, the following case study of Hurricane Katrina (hereafter "Katrina") examines the storm's effects on U.S. states. It does not address the storm's effects on the Bahamas. To narrow this discussion further, this case study looks primarily at the situation in New Orleans and does not deal with FEMA's role in other affected areas like Florida, Alabama, and Mississippi. Problems emerged with FEMA's crisis management and response to Katrina. Some of the effects of such problems were made public with extensive media coverage of the events in New Orleans following the storm's landfall. Accusations of problems in FEMA's response efforts in all four phases of a disaster emerged from media, academic, expert, and public circles. Understanding both what went wrong and what worked in prior disasters and examples of crisis management allows managers to be better prepared for future crises.

FEMA's mitigation phase of disasters includes efforts to protect areas and populations from potential hazards. The threat of a hurricane hitting New Orleans was nothing new to crisis managers. For years, problems had been developing with the levee system that below-sea-level New Orleans relied on for protection and had been discussed by various experts. More specifically related to FEMA, these mitigation efforts also included training for the scenario of a significant hurricane hitting New Orleans. The development of the Hurricane Pam training exercises (also known as the Southeast Louisiana Catastrophic Hurricane Plan) was a success for crisis managers in FEMA's mitigation efforts. However, the implementation of the exercise and steps taken to improve mitigation after the exercise were less successful at various levels of government. This lack of preparation based on such mitigation efforts made them largely a failure, setting the stage for future problems.

Local Problems Thwart FEMA's Efforts

Without fully realized mitigation efforts, problems quickly emerged in the preparedness phase. Katrina struck Florida as a Category 1 storm on August 26, 2005. The storm made landfall just north of Miami and killed at least six people. When Katrina finished crossing Florida, it hit the warmer waters of the Gulf of Mexico and began to grow in size and strength. As the storm approached the Louisiana and Mississippi Gulf Coast, the number of delays and problems with evacuation efforts quickly mounted. FEMA did have evacuation guidelines in place, but crisis management efforts ultimately failed, as these guidelines do not seem to have been followed at the local level by leaders like Mayor Ray Nagin. This was further complicated by the fact that when evacuation orders were implemented, not all residents did or could evacuate. Not enough transportation was organized to evacuate vulnerable residents who wanted to leave the city (particularly the poor, racial and ethnic minorities, and the elderly), leaving them to shelter-in-place or to make their way to shelters of last resort. Local and other government leaders and crisis managers do not seem to have been prepared to take vulnerable populations into account and to deal with their special needs, such as the lack of transportation or funds to evacuate.

Problems Mount

The storm made landfall on the Louisiana and Mississippi coastline on August 29. It was during and immediately after the storm, the response phase, that many of the widely publicized problems with FEMA's crisis management surfaced. Federal assistance was seen by many as slow to respond. While some responders were on the ground in the affected areas soon after the storm, distributing what aid they could, problems in crisis management quickly emerged. Not enough resources were on hand for distribution, with the amounts of ice, water, and food seen as necessary in planning for such an event with exercises like Hurricane Pam far higher than what had actually made it to staging areas. This lack of resources was complicated by public and media discussion of which resources should be available, where they were or should be distributed, and who was eligible to receive them.

Communication problems emerged at and between different levels of government as people who needed to make important decisions did not

(Continued)

(Continued)
always have the information they needed to do so. And there was a lack of resources, mostly vehicles like buses, to evacuate the residents who had ridden out the storm in the city and its emergency shelters (many of whom were part of vulnerable populations). Better resources and communication were clearly needed at all phases of Hurricane Katrina response in New Orleans, and in other areas, for effective crisis management. Crisis managers must be aware of potential problems such as a lack of response by local leaders and unprepared vulnerable populations in order to be able to effectively manage crises and help residents who need assistance.

resources to initiate response efforts themselves. Next is the local level of emergency response, wherein cities and counties have their own emergency response and management systems in place to aid citizens. Tribes and states are, in turn, in charge of response when local governments are unable to provide enough resources or manpower to deal with a disaster. At these lower levels of government, agencies and officials generally cooperate with other nearby governments and arrange for assistance in times of emergency as needed. Such agreements are usually made well in advance of crises. Finally, there is the federal level of response, which is used when lower levels of government cannot manage a crisis on their own. Crisis managers at each level should know their area, potential hazards that may affect it, and how they need to interact with and ask for assistance from other governments they have prearranged agreements with or from higher levels of government.

Following the terrorist attacks of September 11, 2001, FEMA became part of the newly formed Department of Homeland Security in 2003. This marked a general shift in the government about the focus of crisis management. Instead of focusing primarily on disaster response, much of the government's focus turned to terrorism preparedness.

Over the years, FEMA has been criticized at several points for failed crisis management efforts. In 1992, FEMA faced significant criticism for its response to Hurricane Andrew. The agency also was widely blamed for the significant problems in disaster planning, emergency response, and crisis management that were made public by nearly 24-hour news coverage during and after Hurricane Katrina in 2005. Following each such occurrence, government officials and agencies initiated reviews to determine what had gone wrong and how FEMA should address these issues. The aftermath of such review post-Katrina was a new public law, the Post-Katrina Emergency Management Reform Act, in 2006. The Post-Katrina Act directed FEMA to create a National Preparedness System for response to all types of disasters, including natural, human-made, and attack.

The Post-Katrina Act follows on a history of FEMA's efforts to encourage cooperation and coordination among various levels of government, nongovernmental organizations, and the private sector. Such cooperation and coordination are critical to effective crisis management. Without cooperation and coordination in communication, resource distribution, planning, and other critical disaster mitigation, preparedness, response, and recovery efforts, crisis management does not work to the greatest benefit of everyone affected by disasters.

Financial Risk Management in Higher Education

Why would a rational person decide to take on a mortgage for a home that she or he cannot afford? Why would a rational decision maker from a reputable financial institution provide a mortgage to that person knowing that she or he cannot afford it? As demonstrated throughout the recent real estate boom in the United States, as well as through the research of various behavioral economists, rational people make irrational decisions, and oftentimes these decisions are based on incomplete information. No person or institution is immune to this tendency. Consequently, it is absolutely essential for both individuals and institutions (that is, groups of individuals) to develop strong and scalable practices for managing financial risk (that is, the possibility of downturns that could potentially lead to financial insolvency). In the case of higher education, financial risk management plays a key role in helping guide the decisions of college and university leaders to ensure the continued viability and positive societal contributions of their institutions.

In an ideal world, financial risk management would be standardized and incorporated into regular budgeting and planning processes of higher education institutions. Instead, however, these exercises tend to stem from sudden or unexpected needs to consider significant changes to the budget and financial plan. The changes driving an increased focus on financial risk management are usually higher level and strategic in nature, and may have goals such as growth and institutional development (as in the case study), a refocus on the organizational mission, and/or the mitigation or avoidance of major obstacles or issues facing the institution. The driving motivation aside, once financial risk management is made a priority for a higher education institution, the facilitating processes and tools (technology) should be (1) designed in a comprehensive manner, (2) built to allow for dynamic modeling across multiple fiscal years, (3) flexible enough to adapt to a wide range of ideas and potential modifications to current financial plans, and (4) fully integrated with current financial plans so that potential changes in key financial metrics can be modeled.

Once the processes and tools for financial risk management are put in place and the modeling is performed, the results of the exercise must be effectively summarized and appropriately communicated. Although elements of the approach to the summarization and reporting of results may vary greatly by institution, there are a few key tenets that every institution should maintain. First, graphics should be used to summarize the results. This is particularly helpful when dealing with large and complex financial data sets. Second, the results should show the potential financial impacts over a long-term period of time (preferably 10 or more fiscal years), and third, the potential impacts should be compared against the current (baseline) financial plan and external benchmarks over that same period of time. In terms of communicating the results to the board and senior management of the institution, the chief financial officer (CFO) should coordinate and develop the communication strategy with the executive leadership of the institution (for example, the president, executive vice president, and provost).

Looking Ahead

In the case study, the university's integrated and comprehensive approach to the financial risk management exercise provided coherent and empirical analysis to help guide leadership to

Case Study: Financial Risk Management at a Large Private University

Recently, at a private university on the east coast of the United States, large in size and well established, university leadership and the board of trustees endeavored to perform a large-scale financial risk management exercise to strengthen and further develop this area as a cornerstone to its comprehensive risk management practices. The university, for the most part, had emerged from the financial crisis of 2008 without many lasting negative financial impacts. At this tuition-driven institution, applications and enrollments continued to rise, along with the academic quality of the student body. Recognizing this as a unique opportunity and environment for growth, the university's top leaders and the board quickly moved forward to develop a comprehensive strategic plan to accelerate growth in key areas and disciplines. As the planning process evolved, the university's office of budget and financial planning was tasked with gathering, organizing, and projecting all of the foreseeable financial impacts of the forward-looking, 20-year strategic plan. The plan, which included both physical and operational (programmatic) investments, needed to be integrated with the university's existing financial plan. This meant that every potential financial impact needed to flow through the university's existing 10-year financial model in order to show the incremental impact of any combination of the strategic decisions being made.

Method

A fairly simple, Microsoft Excel–based financial model was built to (1) list each of the strategic decisions being weighed, along with its estimated annual financial impact, (2) allow selection of any combination of those decisions (line items), and (3) aggregate the net impact of those selections on some of the university's key financial metrics. Considering the key financial information provided by the balance sheet, the statement of activities (income statement), and the statement of cash flows in the university's consolidated financial statements, the CFO for the university advised the president, the board, and other senior university leaders that the focus for evaluation of the plan should be on three key metrics: (1) liquidity (defined as the university's cash on hand and short-term investments that could be liquidated in 30 days or less), (2) debt (defined as the university's long-term outstanding debt), and (3) leverage (defined as the ratio of expendable financial resources to debt). The impacts that the plan would have on these three metrics would, as the CFO explained, be key determinants of the university's ongoing financial health. When taken together, the metrics capture fluctuations in net income flows, demonstrate the institution's ability to pay its debts, and project forward changes in assets and liabilities. Consequently, these metrics also weigh heavily in assessments performed by the major debt-rating agencies.

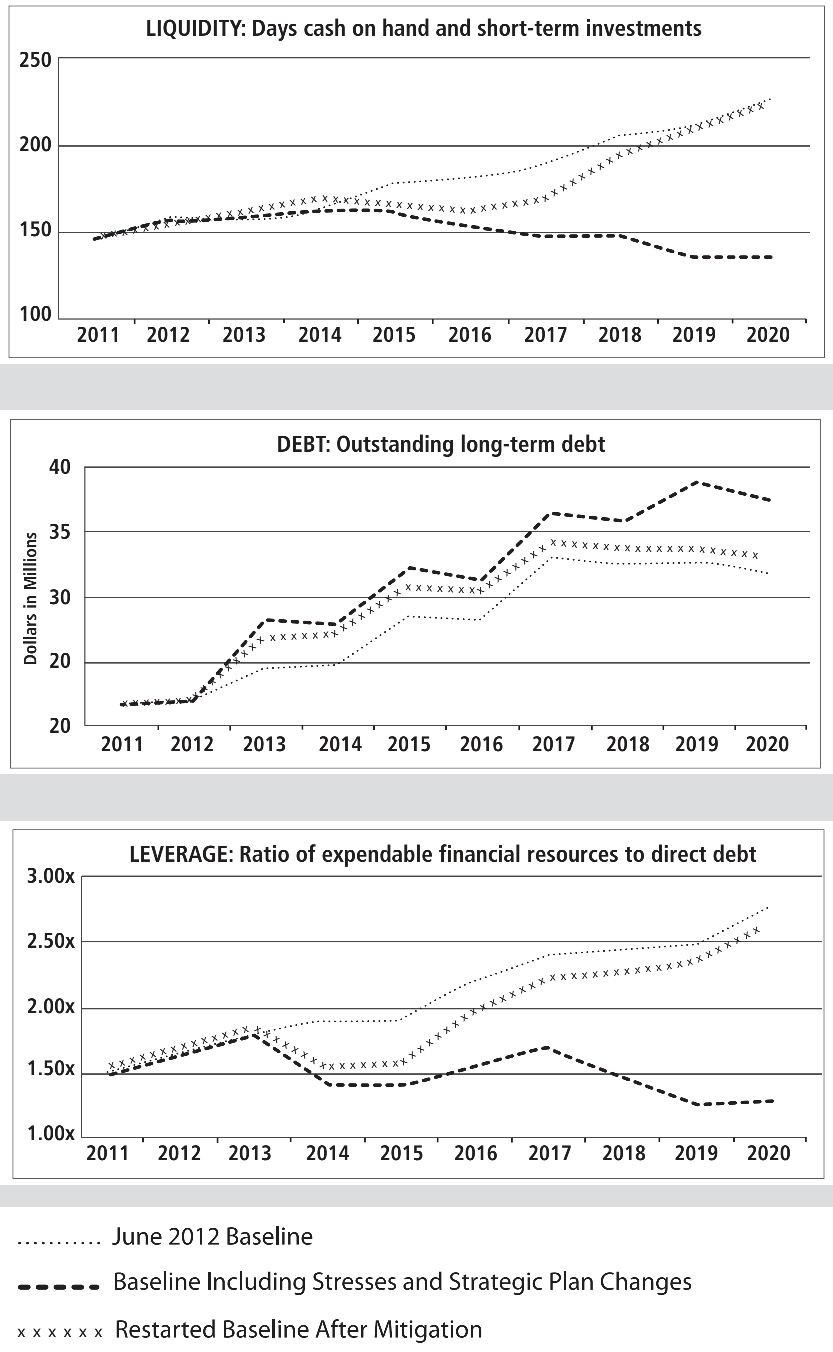
Stress Tests and Mitigation Strategies

Considering the heightened economic risks in the current environment in which the leaders of the university were planning for future growth, various "stress tests" were developed to dynamically demonstrate the financial impacts that might result from minor, moderate, or severe financial stresses on the university. Using the same three metrics for evaluation of the strategic plan (liquidity, debt, and leverage), the office of budget and financial planning worked with the CFO to develop an assortment of "stresses" (for example, reductions in planned revenue growth and greater-than-planned increases in various categories of expense). The same methodology for modeling the potential impacts of the strategic plan was employed for testing these stresses. This enabled the planning team to demonstrate the impacts of items from the strategic plan alongside the impacts of the stresses.

In addition to modeling the impacts of the strategic plan and the stresses, mitigation strategies were also identified, and their positive financial impacts were estimated and made available for selection in the model. Mitigation strategies included items such as reductions in various categories of controllable expenses, increases in controllable revenues, and asset sales, as well as "off ramps" and "on ramps" to the strategic plan. The "off ramps" and "on ramps" to the strategic plan included reductions and eliminations of certain strategic plan items, as well as new potential revenues that could be captured to offset the increases in allocations of financial resources required by the strategic plan investments.

Results and Communication

Through the use of these three line graphs, the planners were able to show how the key financial metrics (liquidity, debt, and leverage) would shift over time (over the course of 10–20 years) depending on the selections chosen from the strategic plan items, stresses, and mitigations. Results were summarized in a presentation that outlined the approaches taken, the processes used, and the logic behind the decisions made to arrive at the desired results. The executive vice president and the CFO then presented the findings to certain key and active members of the board of trustees' finance committee. After incorporating their feedback and recommendations, a final document was presented by the president and CFO to the full finance committee, and then ultimately to the full board of trustees during the annual budget cycle.



make rational and informed decisions about the future of the institution. It will be equally, if not more, important for the university to continue analyzing its current financial health and risks based on the same metrics (liquidity, debt, and leverage) used for the evaluation of the short- and long-term plans. As the strategic plan is implemented and operationalized, and as the university experiences financial fluctuations anticipated by the stresses and mitigations, it is essential to continue to monitor the key financial metrics to allow decision makers to recommend corrective actions and changes in course to continue to best guide the university to achieve its goals.

In the broader spectrum, the economic and political climate in the United States continues to create an environment in which not-for-profit higher education institutions must look beyond their intrinsic values and begin to extrinsically prove their worth to the public. From this flows an increased focus on transparency and accuracy of financial data and stewardship. Thus, it is critical, now more than ever, for higher education leaders to comprehensively evaluate and effectively manage the myriad financial risks associated with maintaining current operations and planning for the future of their institutions. Proactive and consistent measuring and testing of the financial health of higher education institutions, for both the short and long term, is essential to the continued success and value proposition of such enterprises.

Although the focus of this article is on financial risk management at higher education institutions, the author acknowledges that effective enterprise risk management must encompass the management of other types of risk as well, such as operational, regulatory, and reputational. Financial risk management should accompany and be integrated with the management of these and other types of risks.

Fink's Crisis Life Cycle

Steven Fink's model charts the life span of a crisis, documenting in sequential stages distinct communication constraints and demands faced by organizations. Thus, the model has predictive power that aids in both crisis response and crisis planning. The model is also widely applied by crisis communication scholars.

Business-Oriented Focus

Although fitting for other crisis types, Fink developed his model specifically from a "business-oriented point of view." From this perspective, organizations are in a potential crisis situation when the event is doing the following:

- Escalating in intensity
- Falling under close media or government scrutiny
- Interfering with the normal operations of business
- Jeopardizing the positive public image presently enjoyed by the company or its officers
- Damaging a company's bottom line in any way

Fink sees crises as "turning points" or crucial moments for organizations where the situation is either going to improve or escalate in severity. If recognized and resolved, events never mature into full-blown crises. If, however, problems escalate into a crisis, the event follows Fink's four stages.

Disease Analogy

Using an analogy of human illness, Fink establishes four sequential stages in "the anatomy of a crisis." As with any crisis stage model, time is an imprecise variable. Fink's four stages can unravel in a brief amount of time, or years can pass before all four stages are manifest. If an event has truly reached the crisis level, however, all four stages must occur.

1. ***Prodromal stage crisis stage:*** Prodromes are symptoms in the human body that, if recognized and treated early, can prevent a serious disease from developing in a patient. Likewise, prodromes in organizations are signs of serious risks that, if

unrecognized or unattended, will escalate into crises. Some prodromes are recognized, but no action is taken. This failure to respond may result from excessive bureaucratic structure or unethical behavior. For example, Fink explains that officials received warnings of potential problems at the Three Mile Island nuclear power plant more than a year before the near meltdown at the facility. An investigation revealed a decision-making structure that impeded the facility's ability to respond expediently. In contrast, Peanut Butter Corporation of America received a clear warning that its peanut paste, an ingredient sold to many companies, was contaminated with salmonella bacteria. Yet the organization shipped the product, contaminating hundreds of products and infecting thousands of consumers. Finally, prodromes may be so subtle that they are nearly undetectable. Such warning signs are typically recognized retrospectively during the chronic phase of the crisis that is discussed in stage three.

2. ***Acute stage crisis stage:*** Fink characterizes the acute stage of the crisis as "the point of no return." By this point, some damage has already occurred. The question then becomes how much worse will the situation get before conditions improve? Observers often mistakenly assume the acute stage is the entire crisis. For example, when an airplane crashes, the crash itself and the immediate response constitute the acute phase. Yet, the crash itself is only the beginning of an intense investigation by regulatory agencies and complex legal challenges.

The acute stage is typically the shortest duration of Fink's four stages. A plane crash, for example, typically has an acute phase of several hours. Some acute phases are much longer. For example, conditions continued to intensify for days after the levees were breached in New Orleans. The Deepwater Horizon oil spill in the Gulf created an acute phase for BP that lingered for weeks. Despite the uncharacteristically long acute stages for these two crises, they were, by comparison, much shorter than the other phases of the two crises.

3. ***Chronic stage crisis stage:*** Using a vivid metaphor, Fink describes the chronic stage as the period during which the "carcass gets picked clean." Investigations by relevant government agencies, audits, exposés by the media, lawsuits, and extended public relations campaigns designed with hope of repairing the organization's image typically appear in the chronic stage. Because the acute stage is past, those participating in the chronic stage have the luxury of time. Investigations can go on for years, making the chronic stage the longest in Fink's four-stage model.

Internally, the chronic stage is where organizations learn from the crisis. A meticulous analysis of what the organization did right and what it did wrong enables the organization to fortify itself against future crises. Those organizations that rush through this self-assessment process are more likely to experience similar crises in the future.

4. ***Crisis resolution stage:*** Continuing with his illness analogy, Fink declares that the resolution stage occurs when "the patient is well and whole again." Once a prodrome is identified, a crisis manager's goal is to reach the crisis resolution stage as quickly as possible. Each misstep taken by the organization during the crisis, either intentionally or unintentionally, prolongs the other stages of the crisis. In fact, the burden of the crisis is so overwhelming for some organizations that they are dissolved before ever achieving resolution.

Application

Fink's model has been applied to a wide variety of crises over the past three decades. Scholars typically use Fink's stages to characterize the progress organizations have made or failed to make toward resolution. For example, the model was used to examine the troubling response of the Roman Catholic clergy to accusations of sex abuse, questionable responses to prodromes in the coal industry, the September 11, 2001, terrorist attacks, and the SARS outbreak. Scholars have also used the model to structure their theoretical analyses of cultural issues in crisis communication, general preparedness strategies, and building collaborative relationships in crisis planning. These diverse applications testify to the model's durability and flexibility in contributing to our understanding of crises and effective crisis communication.

Fires

Over the centuries, fires have induced significant impacts on lives, property, cultural heritage, our environment, and continuity of operations of affected businesses, whether a result of human or natural causes. The magnitude of these events and the way these crises have been managed has evolved over the years. Centuries ago, for instance, fires could develop, spread, and consume large portions of cities (e.g., the great fires of Rome [64 B.C.E.], London [1666], and Chicago [1871]). These fires each destroyed large sections of their respective cities. Natural disasters have also led to large fires and extensive damage. This includes fires following earthquakes (e.g., 1906 San Francisco or 1995 Kobe), where fires caused relatively as much damage as the earthquakes themselves. Devastating fires have also been initiated by humans. This includes during war. This has resulted in considerable damage, including during World War II (e.g., Dresden, Tokyo, and London). Whether resulting from an accident or human-made, these "urban" fires once grew to immense proportions. To manage these crises better, building and fire codes over the last century have helped reduce these citywide conflagrations, and fires have been contained typically to the building of origin. However, during this period, there were numerous large life-loss fires that led to significant changes to building codes, laws, and ordinances to further address the need for additional life safety–related measures. These disasters have included the fires at the Iroquois Theater (1903), Triangle Shirtwaist Factory (1911), and Coconut Grove Night Club (1942). Crisis management has thus evolved over the centuries, typically through experience and past crises, yet there is more that can be done to prevent and mitigate these events from becoming large crises.

Planning and Mitigation

An important component to crisis management is planning in advance. This includes developing fire strategies and fire prevention plans. Fire strategies can be developed in accordance with building and fire codes, which should be developed, implemented, and enforced by country, regional, and local jurisdictions. Codes typically address various fire and life safety mitigation measures including egress, compartmentation, detection/alarm and suppression systems, firefighting equipment, and protection of the structure, among other requirements.

Codes need to address all types of buildings and occupancies, so their requirements can at times be generic and not tailored to specific buildings or an owner's specific needs (e.g., addressing unique hazards, protecting vulnerable collections, or preserving historic artifacts and buildings).

Performance-based, risk-informed codes in recent years have made significant progress in helping fill this gap. These help provide an approach to address specific objectives, goals, and hazards through risk assessments that result in the development of more tailored and integrated mitigation and prevention measures to help manage crises and keep disasters from occurring.

Crisis Management Training for a Fire

The concepts of creating awareness throughout a community and fire safety education for the public can help limit an event from escalating into a significant crisis. Awareness and crisis management training can have significant returns on investment in reducing the magnitude of the crisis. A few key areas are as follows.

Emergency evacuation training of occupants is important. These efforts help familiarize occupants with methods for detection of an incident, notification and communication methods during crises, locations of exits, evacuation routes, discharge areas, and gathering points outside

Explosions and fires erupt at the Barton Solvents facility in Valley Center, Kansas, July 17, 2007. The incident led to the destruction of the facility, projectile damage offsite, and the evacuation of 6,000 residents. Firefighters used a combination of foam and water to fight the massive blaze. The U.S. Chemical Safety Board, which found the most likely cause to be a static spark that ignited the air–vapor mixture inside a filling tank, released a case study and educational safety video depicting the sequence of events.

buildings. This training helps also to familiarize occupants with various evacuation strategies, as there may be a need to move only some of the occupants immediately in the vicinity of the fire first and not congest the exit routes, then evacuate others. Alternately, occupants may be required to relocate rather than totally evacuate, as in a high-rise fire for occupants on upper levels.

Emergency team drills can have a significant impact in familiarizing all with types of events that may occur and actions that need to be taken. This includes drills for occupants, fire wardens, and local emergency responders. These drills help familiarize the local responders with access to the site, locating the fire command center within the building, planning access to upper floors, locations of exit stairways, and other factors critical to their success in carrying out their duties.

It is also important to have the appropriate type of equipment for emergency responders onsite and in the appropriate locations for easy access. This equipment needs to be appropriately inspected, tested, and maintained so that it is available during an event.

Crisis Management and Emergency Response

Time is critical in managing a crisis. For a fire, it is important to detect a fire as early as possible and to notify appropriate personnel, including building management, the crisis management team, occupants, and emergency responders. Getting the emergency responders not only to the site as soon as possible but access around the building, into the building, and to the upper levels (e.g., stairs, elevators) reduces the overall response time to help evacuate occupants and to begin managing the incident before it has a chance to grow and develop further (e.g., contain, control, extinguish).

Setting up Incident Command Centers, communicating effectively with occupants and other emergency response teams, establishing staging areas for equipment, and allowing search and rescue operations to be conducted are all critical components in the early minutes of responding to a disaster that are important to the successful management of a crisis involving fire.

Once the fire has been suppressed, the emergency responders can begin to undertake salvage efforts to help ensure the fire is out and all occupants are accounted for. During this period, it is important to have appropriate professionals available to undertake immediate damage assessments to the site and building(s) as to its structural soundness, as well as the overall environment within the building and whether it is safe to conduct further salvage efforts or if there is a need for decontamination. Further assessment regarding damage to contents and business operations can be made as well.

Recovery From a Fire Event

Following a fire-related crisis, it is important that a crisis management plan be in place that details the recovery and restoration efforts. This should include plans for further detailed damage assessments, implementation of business continuity plans, public relations–related activities to keep the press and public informed of critical information as well as appropriate management of public perception, and conducting restoration plans so that one can return to operations as soon as possible from a fire event. These are all critical to properly manage fire-related crises.

Floods

A flood is an overflow of water onto landscape or urban settings that are usually dry. Floods are generally categorized by the physical source and properties of the excess water (e.g., river, lake, ocean, or debris flow), but the causes, effects, and dynamics also provide further criteria for flood characterization (e.g., storm surge or tsunami flooding, dam break, urban flooding, or flash floods).

The significant impact that inundations have on the territory, their always higher intensity and frequency, and their impact in economic and social terms pose floods as one of the major threats from the international to the local scale. As a result, crisis management must necessarily and carefully consider floods and develop specific preparedness, prevention, mitigation, monitoring, response, and emergency plans to limit their devastating effects.

Flood Categories, Causes, and Effects

Flood types are mainly associated with the natural feature and the physical process (dynamics) that originate the inundation phenomenon.

In particular, riverine and coastal floods are determined, respectively, by the excess water flow derived from fluvial channels and by the ocean surge that may occur, respectively, under severe hydrologic (e.g., rainfall) and climatic (e.g., strong winds, tropical cyclones) conditions. Those different and diverse factors may also combine, as in the case of estuarine floods, where the ocean and fluvial waters interact. Floods may be indirectly caused by another hazard, as in the case of a submarine earthquake (tsunami) or the collapse of a water retention structure (e.g., levee, dam).

A different categorization method pertains to the analysis of the flood dynamics that is mainly based on the duration and speed of the event, with slow floods usually driven by heavy rains and/or snowmelt on mid-large rivers and fast (flash) floods caused by convective precipitation (e.g., thunderstorm) in small river basins. The concentration of sediments that propagate with the flood wave is another factor, with mud and debris flows that mainly characterize alluvial fans and mountain areas.

The passage of the flood through the territory has often devastating direct effects connected to the physical damages to human properties (e.g., roads, bridges, buildings, agricultural fields, and industries) and casualties but also significant indirect effects such as business interruptions, the evacuation of affected people, water-driven diseases, and other hygienic issues. The negative environmental, economic, and social effects of floods are often temporary, but they may also last for months if an effective crisis management plan hasn't been developed and preliminarily implemented for tackling this natural disaster in both the pre-event and post-event period.

Flood Crisis Management

Floods are natural (extreme) events that cannot be avoided in most cases. Low-lying river valleys and coastal areas have always been the subject of recurrent inundations with overland river flows that in ancient times had also been the source of beneficial (fertilizing) effects, as in the well-known case of the Nile River flooding. Nevertheless, in modern times, urbanization and the increasing human activity and presence are contributing to an increase of the negative impact of floods, and the sustainable development of the territory cannot avoid considering the maximum inundation extent and dynamics as major factors affecting urban expansion and land use plans. Thus, even if the adverse impact of floods cannot be neglected, significant mitigation may be achieved by effective flood risk management that should include a preparedness, prevention, mitigation, monitoring, response, and emergency plan.

Preparedness means that people living in flood-prone areas are properly informed and prepared on how to behave in case of flood. A prevention plan aims to mitigate the effects of floods by decreasing the presence of construction and people within potentially inundated areas, not only by implementing evacuation plans, but also by promoting sustainable urban and rural development practices. In order to implement efficient evacuation and urban/land development plans, it is necessary to develop flood monitoring/warning and flood zoning projects. These nonstructural flood protection measures of people displacement and constrained urban development are generally implemented by advanced flood modeling and mapping studies that are able to forecast flood events in real time and to identify the extension and intensity associated with a predefined design flood scenario. Flood simulations are also used for designing structural measures for flood impact mitigation by means of dams, levees, seawalls, and any other structures able to intercept, convey, or store flood waters and prevent them from flowing through vulnerable areas. Whereas flood preparedness, prevention, and monitoring are active (pre-event) measures, flood response and emergency response represent the reactive actions that civil protection managers use during the event and the post-event phase to guide people to recover and reestablish the pre-flood conditions on the territory.

Food and Agriculture Organization of the United Nations (FAO)

The Food and Agriculture Organization (FAO), a specialized agency within the United Nations for international efforts on food security, was formed in 1945. Despite criticisms from some quarters during the FAO's history, it can be argued that the agency has been central in defining the direction of agricultural production and food security and seeking avenues for managing food crises worldwide. Since the formation of the Food and Agriculture Organization, there has been a plethora of challenges that have threatened or had direct impact on food security and agricultural production. Thus, the focus on FAO is unlikely to shift as situations singly or in combination trigger events that threaten to grow into food crises. As the world population has grown to over 7 billion, the organization at the center of food security has repeatedly faced challenges for managing crisis in the areas of food security and agriculture. How the world manages to negotiate crisis, prepares for and responds to food crisis becomes increasingly imperative, as the world expects the Food and Agriculture Organization to take the lead, with its Latin motto *Fiat panis*, meaning, "let there be bread."

Crisis Breeds Crisis

Political and social instability have often been closely linked to food insecurity. Well-founded or imagined fears regarding food insecurity can lead to social instability at regional, national, or local levels. Following fires in one of world's leading wheat-producing areas in central Russia in 2010, coupled with adverse weather patterns impacting food exports from Australia, food prices skyrocketed. As a consequence, unrest erupted in some parts of the world, including protests against bread price rises in Maputo, the capital of Mozambique, from where it was reported that about 280 people were injured as a result of unrest. Around the world in 2007, food shortages were some of the most severe in a generation, leading to riots from Mexico to Bangladesh and the collapse of governments in some parts of the world. The FAO was key, or at least seen to be key, when dealing with the crisis of food security from its headquarters in Rome. The opportunity and challenge of influencing decision making and international and national policy, as well as dealing with a range of complex interactions and triggers of food insecurity, was critical.

International Markets

One challenge that the Food and Agriculture Organization faced relates to how it could deal with food production that had historically been organized around local and national levels. Small-scale agricultural production based on local needs and subsistence farming was the norm in many countries, and self-sufficiency was promoted at a local level. However, globalization, partly defined as the harmonization of social, economic, and cultural practices, has over time impacted localized agricultural practices in favor of mass crop production. Mass crop production practices have generally been welcomed by proponents of globalization, free trade, and mass production, who argue that small-scale and localized agricultural production practices had failed to meet the changing needs of modern consumers.

Furthermore, proponents of free market principles have argued that the availability of food is likely to increase through mass production and free trade. There is indeed some evidence with regard to the benefits of globalization and liberalized agricultural markets. Critics of liberalization and globalization do, however, argue that these benefits have been overemphasized and are fraught with difficulties. Sensitivity to speculation in international food markets and food price increases have been cited as major shortcomings of globalized food systems and markets. Indeed, speculations on international food markets and responses by grain-exporting states have included the banning of cereal exports, resulting in catastrophic effects on food-importing countries. Following the 2007 food crisis, the FAO launched its Initiative on Soaring Food Prices to help small farmers boost their output and thereby earn more income. Along with the European Union, the FAO signed an initial aid agreement of about US$140 million to assist small-scale farmers who had been adversely affected by rising food prices.

Under the Special Programme for Food Security, the FAO engaged in the ambitious goal of halving the number of the hungry in the world by 2015 as part of the Millennium Development Goals.

Global Warming

Despite such efforts, the FAO is faced with a much wider debate relating to global warming, which as a phenomenon has been advanced by some scientists to be probably one of the greatest threats that the planet has ever faced. Its projected impacts relate to a rise in global temperature that might trigger erratic weather conditions. There are claims and counterclaims about its impacts on agricultural production. Its effects have been identified as ranging from the melting of glaciers to desertification to lowering of groundwater levels. Erratic weather conditions have been attributed to the increasing destruction of the ozone layer because of the level of carbon released into the atmosphere as a result of human activities, stripping the ground of its vegetation cover, the growing use of fossil fuels because of the increase in less environmentally friendly industries and car use, and the increase in methane gas from farm animals and the clearing of forests for agriculture using fires.

Although there has been less than unanimous consensus among scientists about the veracity of claims of human activities' impact on global warming, there have been some concerted efforts to formulate policies and make decisions to reduce carbon emissions. There has been an increasing interest in developing renewable energy sources instead of fossil fuels. Given the large volume of vehicles on Earth, vast pieces of land have been turned into growing crops such as sugarcane with the aim of producing ethanol. These efforts to mitigate disasters brought about by global warming have paradoxically been blamed for growing food security threats and crises. As biofuel crop production increases in acreage, food security has been said to be threatened by decreases in food crops, resulting in reduced annual food outputs. Indeed, this discussion is also about land use.

Land Use and Population

Another challenge facing the FAO is that food insecurity and resultant crisis are increasingly being attributed to the increase in world population as the most likely trigger. Surprisingly, little effort has been made at both international and national levels to address this issue, perhaps because of cultural sensitivities in some developing countries and declining populations in some developed countries. It has been argued that the world population is outstripping the rate at which the planet can be sustainable. Population issues and family planning have tended to be sensitive issues, and thus very little motivation has been shown either by states or by international institutions to discuss them. Rapid deforestation, the clearing of land that had previously been left untouched, has become commonplace as people seek to increase farm produce in order to sustain their families. Thomas Malthus's *Essay on the Principle of Population*, published in 1798, registered some of these concerns relating to the effect of population increase and its tendency to overwhelm food production.

The debate with regard to the increasing world population has opened a host of claims for solutions. Some have argued that scientific and technological advancement mean that the world can care for its growing populations through innovation. These claims suggest that biotechnology, including the development of genetically modified food, has the potential to address the problem of increasing populations, not through increased farmland but through increased yields. Thus, hybrid and modified varieties have been promoted to address this need. Indeed, scientific innovations have meant that the mass production of fish in farms has become increasingly possible. Furthermore, scientists have argued that if the world is indeed warming up, leading to an increase in drier soils, innovation may help in developing new crop strains that can withstand reduced soil water content and higher temperatures.

Despite evidence that points to some beneficial scientific innovations, critics of population increases have argued that the solutions do not lie in increasing production of farm produce but rather in decreasing the population. Similarly, fears have been raised about genetically modified varieties of fish escaping and cross-breeding with wild varieties of fish. Thus, the increase in genetically modified crops has largely been fiercely opposed in parts of Europe and the developing world. This is, however, not the only problem, for increasing need for both food and economic progress brings with it other challenges.

Crisis Management

The FAO, despite considerable criticisms, has arguably been active in meeting some of its objectives, including mitigation, preparedness, response, and recovery, through a range of means, as discussed below.

Partnerships and crisis management: Effective crisis management requires compliance through cooperation and standardized approaches to emergencies. The FAO has forged partnerships with a range of stakeholders in food, including the World Food Programme (WFP) and the International Fund for Agricultural Development (IFAD). It has often worked closely with the European Union on issues relating to farmers and food security. The training of farmers in integrated pest management under the Farmer Field Schools with support from countries has widely been acknowledged as a success.

It is important to understand the mandates of these three key agencies, which have related though somewhat distinct mandates that are complementary in many ways. This is also evident in the level of cooperation they have increasingly pursued. The FAO is the lead agency for technical expertise in food security, fisheries, agriculture, forestry, and rural development. IFAD's mandate is unique when considering the range of roles played by international financial institutions. Central to IFAD's mandate is to fund rural development projects aimed at improving the nutritional levels and living conditions for the poorest populations. The mandate for the WFP is that it is the leading emergency food aid agency of the United Nations. The WFP also assists with building structural assets and is involved in the promotion of self-reliance among poor communities.

In 1994, the Emergency Prevention System for Transboundary Animal Plant Pests Diseases focused on the control of diseases, including foot-and-mouth disease. As early as 1952, the FAO organized an international forum, the International Plant Convention, aimed at coordinating technical assistance with regard to pest outbreaks and maintaining a catalogue of pests. The Alliance Against Hunger and Malnutrition is an initiative developed by the FAO to address hunger and malnutrition, whereby local, international, and regional institutions are connected to share strategies for combating hunger.

Information systems and crisis: Robust crisis management systems, whether at the national or international level, require effective communication and information management. The Food and Agriculture Organization established the Global Information and Early Warning System (GIEWS) to monitor world food supply and demand. This is a useful tool, as early warning (of impending emergencies) furnishes the international community with invaluable and timely information. The United Nations organization also has its database, the FAOSAT, which covers statistics on agriculture, fisheries, forestry, land use, and population, among other areas.

Training and capacity building: Training and capacity building are critical to crisis management. The FAO has been very effective in some cases, including training farmers. Global partnership initiatives for plant breeding and capacity building are critical to crisis management. They create a network of critical stakeholders with a view to increasing capacity building for plant breeding. This is a mechanism to minimize the occurrence of crisis, including volatile food prices.

Conclusion

Despite criticisms of the FAO, a few critical factors have been established in relation to challenges of food and agriculture production: that food security is critical to social stability, that global markets and food chains impact the food needs of the population, that human activities are adversely affecting the environment and in turn affecting agricultural production, that technological advancement has some possible roles to play in food and agricultural production, and ultimately, that there is a growing need to strike a balance between economic needs and sustainable development.

Effective management demands effective systems not only within FAO management and operations but nationally, regionally, and internationally. Yet the food industry faces a complex system of interactions in terms of food markets, speculations, and anti–genetically modified crops sentiments of those motivated into the market by gains and climate change. Thus, crisis in the FAO seems to demand a much wider understanding of interests within the food industry and beyond. Ultimately, this discussion relates to the resilience of agricultural systems that can be enhanced by responsible policies at national and international levels. Food crisis is not confined within national borders.

Most disasters are not confined to simplistic national borders. For instance, global warming does not confine itself to national borders. Similarly, epidemics, including mad cow, foot-and-mouth, and Newcastle animal diseases, cannot realistically be confined within national borders. Global agricultural production problems call for local, national, regional, and international global solutions. International food markets have assumed an increasing role in food supply systems. Growing cross-border trade does not present only opportunities but also increased supply chain risks. Disruption to supply chains, market speculation, and food safety problems demand international agricultural solutions.

In the end, this discussion relates to the need for states and bilateral and international institutions to formulate coherent and integrated solutions aimed at disaster mitigation while being equally responsive to immediate human food needs. Thus, this demands formulating resilient national and international institutions facing agricultural production.

Food Security

Worldwide food security means that there is enough food in the global supply and that all people always have access to nutritious and affordable foods. A food-secure individual has access to enough food items, nutritionally and preferentially, to lead a healthy lifestyle. Food-secure households are those in which all members are assured consistent access to food items that meet dietary requirements. The notion of food security is conceptualized as adequate food provision through culturally acceptable methods. In other words, people are not forced to obtain food through violence or stealing, rely on emergency food resources, or employ other nonsustainable reactions to food insecurity. Lack of food security is an ongoing crisis, and organizations around the world endeavor to end growing trends of food insecurity.

The notion of food security is often misunderstood to mean food safety. Food safety initiatives deal with the hygienic handling of food in order to prevent foodborne illnesses. Resources like the National Center for Food Protection and Defense (NCFPD) focus on food safety. The NCFPD extends our understanding of and strategies for food protection through programs like modeling, education, and research in risk communication. Although food safety is not an accurate synonym for food security, this improper meaning is commonly used.

Food Insecurity

To better understand food security, food insecurity must be explored. Globally, people struggle to obtain adequate food for nourishment. Inability to consume sustaining food occurs for a variety of reasons: poverty, war-induced famine, diminished accessibility, disease, limited harvests, droughts, decreased food supply, and ignorance about wholesome food choices. Some individuals, households, and regions are more vulnerable to food insecurity because of social, political, economic, or environmental circumstances.

Poverty is a leading cause of food insecurity—both malnourishment and chronic hunger. Impoverished individuals and households lack the necessary resources to purchase foods. Buying nutrient-rich food items like meat and milk is often more expensive than purchasing grains or starch foods. Thus, impoverished households struggle to gain regular access to nutritious foods, correlating poverty with food insecurity.

Wars, warlords, and government damage to their own nations are other causes of food insecurity. Reports of unjust political regimes using war to gain compliance from citizens arise from around the world—tales of warlords intercepting United Nations (UN) supplies in war-torn countries and intentionally starving cultural groups into submission. Joseph Stalin's *Holodomor* is a historical example of how a government intentionally created food insecurity (and genocide). Government malevolence and reticence are odious causes for food insecurity.

Diminished accessibility to nutritious foods occurs because of social inequality or economic, political, and agricultural changes. For instance, problems with dwindling harvests affect already-struggling regions, leading to large-scale food insecurity for those who can't purchase imported (expensive) foods. Other examples of diminished access include declines in fish stocks or climate changes that make farming or animal husbandry difficult.

Natural disasters can weaken people's ability to access sustaining foods. Tsunamis, floods, droughts, fires, earthquakes, and landslides are just some of the ways nature creates voids in the global food supply. When foods become unavailable, people's access to necessary food is threatened.

Lack of education and apathy about nutritional foods is another key reason for global food insecurity. In other words, one surprising cause of food insecurity is dietary choices. Individuals and households can consume a large quantity of food and still be food insecure, meaning the food items selected are of poor nutritional quality. Consumption of junk foods, high-sugar items (e.g., sodas, pastries), and other unhealthy food choices can lead to food insecurity.

This does not address all of the reasons individuals and households remain food insecure. Poor budgeting skills, transportation issues, inability to self-farm, hefty bills, regional water deficits, delayed welfare payments, the need to send money home to struggling relatives, and land degradation are just some of the many reasons households struggle to establish food security.

Food Insecurity: A Crisis

As discussed above, food insecurity occurs for many reasons. Food insecurity is a growing global crisis because of its far-reaching implications in social, government, agricultural, and political systems. Some accept food insecurity as a normalcy when in fact it's a colossal crisis, impacting the well-being of countless individuals.

Furthermore, new crises can create or extend existing food vulnerabilities. For example, the decision to become a migrant worker not only separates family members, but also leads to reduced security in terms of daily meals and income for the family members (often children) left behind. Another example includes HIV/AIDS-infected persons. Prevalence of AIDS is an ongoing crisis because it is life threatening and reduces many households to poverty and food insecurity by (1) inhibiting a previously healthy family member from earning income, (2) shifting family resources to HIV/AIDS medications instead of food for the household, and (3) causing food-earning family members to allocate time to care for the HIV/AIDS patient. Migrant workers and the HIV/AIDS pandemic are just two examples of how a compounding crisis disrupts food security or intensifies existing food insecurity.

Global Goal: Food Security for All

Any individual, government, nonprofit organization, or policy maker wishing to effectively take on food insecurity must first understand it and then pinpoint vulnerable populations. In 2009, the Food and Agriculture Organization of the United Nations convened the World Summit on Food Security in order to discuss and problem-solve for the growing threat of food insecurity. This conference, UN partnerships, and goals like "Feeding the World in 2050" are powerful resources for systematically achieving global food security. Problems such as poverty, worldwide population growth, political hostilities, and other compounding issues all cause and interact to create patterns of food insecurity. Responsible individuals, organizations, and governments are joining the strategic fight toward global food security, a goal worth considering and attaining.

Foreign Policy Crises

The study of foreign policy crises has been seen as playing an influential role in the development of a wider set of theories around crisis management. In particular, the literature dealing with such crises was important in shaping early attempts at defining crisis; this work on foreign policy crises served to influence subsequent work in other disciplines. At their core, foreign policy crises are seen to occur where the potential outcomes of the policy are at odds with the aims and goals of the state in a highly stressful and time-limited setting. There have been several seminal studies that have looked at foreign policy crises, including the Munich Appeasement, by P. M. Kennedy (1976) and J. L. Richardson (1988); the Cuban Missile Crisis, by G. T. Allison in 1969 and T. J. McKeown in 2001; and the wars in Iraq and Afghanistan, by D. Byman in 2008 and C. Kaufmann in 2004. Much of this attention has focused on the performance of key decision makers. Foreign policy crises have also taken on a new dimension with the increasing effects of globalization, which generates challenges for governments as they try to regulate and control the actions of powerful multinational corporations. The 2008 banking crisis illustrated the interconnected nature of the banking industry and the difficulties associated with regulating it, and the issue of regulation remains controversial. The continuing problems surrounding the euro have also generated challenges around foreign policies as governments, both within and outside the eurozone, have tried to deal with the demands of the crisis. Against this background, the notion of a foreign policy crisis can be seen to have moved away from its traditional setting to incorporate a wider set of contexts in which such crises can occur.

The scale and diversity of these crises make a full discussion of their implications here impossible and, as a consequence, this article focuses on three particular aspects of research in the area of crisis management that have developed from foreign policy crisis research. These are the performance of crisis decision teams, the role of latent and active error in the decision-making process, and the impact of unintended consequences (emergence) arising from policy making. It is recognized that such a selective approach can be problematic, and the aim here is to point to links into the wider theory of crisis management relating to these three elements, each of which can now be considered in more detail.

Performance of Crisis Decision Teams

The potential consequences associated with foreign policy crises have led to a focus on the quality of decision making within those groups who manage such events and the manner in which they cope with the stress associated with such conflicts. One of the seminal studies of crisis team performance was carried out and published in 1982 and 1989 by Irving Janis, who developed his groupthink concept based on a study of decision making within the Cuban Missile Crisis and other related events. The concept has also been applied to other crises including the Munich appeasement, by S. G. Walker and G. L. Watson in 1989; Vietnam and the Bay of Pigs, by R. M. Kramer in 1998; and various others involving foreign policy–related problems, by F. Bynander in 1998, J. K. Esser in 1998, and T. Forsberg and C. Pursiainen in 2006. These studies have generated a focus on research that has looked at the role of government leaders within this process and the impact that individual psychology or health might have on their decision-making capabilities. David Owen's research in 2006 and 2009, in particular, raised the issue of how senior politicians can be impaired as a function of medical or drug-related ailments and how this might impact decision making both in the buildup to and during crises. The centrality of these leaders within the decision-making process places them both as potential causal agents in the development of foreign policy (and by implication, the crisis, should it occur) and as key individuals in any response to the crisis as it occurs. David Mervin notes in his *Journal of American Studies* article, "Presidents, Precedents, and the Use of Military Force" (1998): "When it comes to the making of foreign policy, and particularly when crises of national security arise, the president, it seems, is inevitably, the main player, the senior partner." This issue of the centrality of key decision makers was also evident in the Cuban Missile Crisis and the debates that followed.

The Role of Error in Decision Making

The role of leaders within the decision-making process leads into the second aspect of foreign policy crises that is important here, namely, the role of latent and active errors. Issues of decision making within foreign policy crises have their origins in a number of celebrated studies. One of the key works was carried out by B. W. Tuchman into the origins of World War I, describing the processes by which decisions taken by world leaders generated a momentum that moved countries into conflict. Tuchman's account of the early months of the conflict highlights the manner in which errors in decision making were able to expose the inherent vulnerabilities within the political environment prevailing at the time. In more current terms, error was embedded in the system, and this latent error was exposed by the trigger event of the assassination of Archduke Ferdinand. The subsequent chain of events was akin to Charles Perrow's later notion of a system that is "tightly coupled" and "interactively complex." Tuchman's work has a wider significance, as it was deemed to be influential for President John F. Kennedy, who had read the book prior to the Cuban crisis.

The issue of latent and active errors also emerged in the aftermath of the second Iraq War concerning the issue of weapons of mass destruction and the possible predispositions of government leaders for regime change in Iraq. The role of the media as a means of framing the issues and shaping public opinion around the legitimacy of the conflict was also an important part of the strategy. In the United Kingdom, the notion of "spin" was seen in the media as a key issue in the aftermath of the war and formed a considerable part of the critique of Tony Blair's decision making.

More critical analysis by Christoph Bluth (2004) and James Humphreys (2005) has suggested that this analysis was more measured than many would believe to be the case. Intelligence failures have also been seen to lie at the heart of the inability to foresee and forestall the attacks on 9/11. The notion of error cost can be seen as an important aspect of foreign policy crises and one that has relevance to other forms of decision-making failure. The reluctance or inability of leaders to see the problems in their strategies is an issue that transcends international politics, although it has been seen to be an important element in the wars in Vietnam and Iraq and also relates to the ways in which multidisciplinary and multifunctional teams make decisions and the psychology of strategic rigidity.

The Impact of Unintended Consequences

The final area of consideration in this brief discussion of foreign policy crises concerns the emergence of unintended consequences arising out of such decisions. These consequences can be seen to relate both to the performance of crisis management teams and to the nature of error in the decision-making process. Given that many policy decisions have implications and effects that are not apparent for many years, these unintended consequences could be seen as an inevitable consequence of foreign policy. For example, the move in Europe to a single monetary policy without an overarching political structure could be seen as a precursor to the current crisis involving the euro. Emergent properties can be seen to emerge from problems where the interaction of elements within the problem space generate issues that have consequences that were either not foreseen or were not seen as credible in terms of likely risks at the time the decision was made. Within the context of foreign policy crises, perhaps the most obvious example is the role of the wars in Iraq and Afghanistan in generating motivations for jihadists to fight against Western occupying powers. This has also been seen as an issue motivating what have become known as home-grown terrorists, a problem that has been seen as especially important in the United Kingdom following the attacks in London and the thwarted attacks on transatlantic airlines. This process, often referred to as "blowback," can be seen as the unintended consequences associated with emergence in complex multilevel policy decisions. The process also relates to that of "error cost," according to David Collingridge (1984 and 1992) and the manner in which policy makers use science and evidence in the decision-making process. In the areas of foreign policy, especially for those problems where intelligence gathering and analysis are key contributors to the decision-making process, the potential for emergent conditions arising out of those decisions can be seen to be high.

Conclusion

This brief discussion of foreign policy crises has sought to highlight three issues that relate to the wider literature on crisis management. This discussion has not been inclusive and has left out issues that some might consider as essential components of any such discussion. This criticism is accepted and is an inevitable consequence of the constrained nature of an encyclopedia discussion. This brief discussion here should be seen as an entry point into debates around foreign policy crises that are both extensive and multilayered in terms of their complexity.

Fraud

Fraud is an action of intentional misrepresentation, committed when a criminal or civil defendant makes a misrepresentation of material fact; with intentional or reckless state of mind; with intent to induce reliance; causing justifiable reliance; that results in damages to the state or a private plaintiff. Action for fraud can be brought criminally or civilly by the state or civilly by a private plaintiff, in tort or contract, or in other specialized instances of fraud, such as in connection with the purchase and sale of securities under Rule 10(b)(5) of the Securities Act of 1933; in connection with the solicitation of proxies under Rule 14(a)(9) of the Securities Exchange Act of 1934; or in various actions for insurance, identity, and other financial frauds. Where fraud is alleged, it must be pled with particularity, such that general allegations of fraud, without sufficient facts, will not survive a motion to dismiss.

Proving Fraud

Though easy to allege, proving fraud is challenging, as it requires proving underlying elements that support a claim for fraud. First, a party alleging fraud must prove the representation amounted to a misrepresentation of material fact. A representation is a misrepresentation when it asserts that something is a particular way when the defendant knows it is not. This can be evidenced by specific actions to mislead, to cover up the truth, or to impede the ability to discover the truth; through a failure to disclose where the law recognizes a duty to disclose; or through a partial disclosure that is misleading. A misrepresentation is material when a reasonably prudent person would consider it important when making a decision or where the defendant has reason to know that this particular plaintiff would consider it important when making a decision. A material misrepresentation concerns a matter of fact when it is not opinion and it can be proven as true or false through use of objective facts.

Second, a party alleging fraud must prove the misrepresentation was intentionally or recklessly made. A misrepresentation is intentionally made when it is communicated for the purpose of deceiving, and is recklessly made when it is communicated with reckless disregard for its truth or falsity.

Third, a party alleging fraud must prove the misrepresentation was committed with intent to induce the plaintiff's reliance. Intent to induce reliance is shown through direct misrepresentation of facts that support an inference of intent to defraud or through indirect evidence of intent to defraud, where the plaintiff is within the expected affected class of persons expected to rely on the misrepresentation at the time it was made.

Fourth, a party alleging fraud must prove they relied on the misrepresentation, and that reliance was justifiable under the circumstances. Where facts would put reasonably prudent persons on notice that they are being deceived, the law imposes a duty to investigate before relying. Where facts do not exist, the plaintiff may rely on an apparently reliable statement without incurring a duty to investigate. In proving that reliance on the misrepresentation was justified, the plaintiff must show that a reasonably prudent person in the same or similar situation would have relied. Where the defendant preys on known vulnerabilities, the requirement may not apply. Where the plaintiff is a professional or possesses special knowledge or experience applicable to the subject matter being misrepresented, justifiable reliance will be judged from the perspective of a reasonably prudent professional with the same or similar qualifications. Additionally, where the defendant possesses knowledge unavailable to the plaintiff, where certain relationships of trust apply; where the defendant has special expertise, or where the defendant has an interest in the transaction under claim of independent authority, the law provides certain presumptions to aid in proving justifiable reliance.

Fifth, parties alleging fraud must prove they suffered damages as a result of misrepresentation by the defendant. Recoverable damages include pure economic loss, damages that flow from the sequence of events set in motion by the misrepresentation, and punitive damages. Recovery for pure economic loss consists of either out-of-pocket expenses, determined by subtracting the value received from the value parted with, or the benefit of the bargain, determined by subtracting the value received from what was promised. The jurisdiction will determine the appropriate theory for pure economic loss. Recovery for damages that naturally flow from the misrepresentation consist of damages attributable to and flowing from the misrepresentation, provided they are not too attenuated to preclude recovery. Punitive damages are also recoverable in an action for fraud but are generally limited to egregious instances that shock the conscience. Where a party prevails on the elements of fraud, there is criminal or civil liability, unless the defendant can defeat it for procedure or raise an appropriate affirmative defense.

Where a party alleges fraud, it must be pled with particularity in the pleadings, or the defendant will defeat it for lack of sufficient facts. When brought without sufficient facts, the defendant will motion for dismissal under Rule 9(b) of the Federal Rules of Civil Procedure, or under the state counterpart where applicable. To survive a challenge under Rule 9(b), a pleading must state with particularity the circumstances amounting to fraud, raising sufficient facts to show that a case for fraud exists. The defendant will also raise evidentiary challenges through pretrial motions to dismiss and/or through evidentiary objections in open court, in an effort to undermine the elements of the claim.

When the plaintiff prevails on procedural and evidentiary matters, the defendant may plead the plaintiff's assumption of the risk as an affirmative defense to liability for fraud. In raising assumption of the risk, the defendant invokes a theory that recovery is precluded, based on the plaintiff's subjective appreciation of the risk and voluntary assumption of it. Where successfully raised, assumption of the risk is a complete defense to recovery, even where the plaintiff prevails on the elements of fraud.

Crisis Management and Vulnerability to Fraud

In the crisis management context, the complexity of response and recovery operations makes efforts especially vulnerable to fraud by claimants, responders, and administering officers alike. Because of competing interests in expediting response and recovery efforts and mitigating the extent and impact of fraud, the inevitable clash of expediting disaster assistance and using comprehensive checks to curtail vulnerability to fraud makes response and recovery ideally suited to fraud. The effect is best seen in numerous accounts of fraud by claimants seeking disaster assistance, responders purporting to provide disaster assistance, and administrators diverting funds to personal interests. When left unchecked in the absence of systematic checks to identify fraud, unwarranted assistance will be paid, funds will be lost, and the efficiency of response and recovery will suffer.

Given vulnerability to fraud in response and recovery, vulnerability can be mitigated by building in systematic checks to identify and address fraud in all aspects of mitigation, preparedness, response, and recovery. By routing claims through independent auditors, utilizing comprehensive supervision of disaster assistance requests, and building accountability into the payment and use of funds paid and materials provided, the risk of fraud can be substantially mitigated in pursuit of effective response and recovery. The preparedness phase is uniquely suited for building antifraud measures into response and recovery ahead of need. Additionally, the risk of fraud can be substantially mitigated by aggressive prosecution for fraud, both individually and collectively, on the heels of response and recovery. Although claims for civil recovery for fraud may be unsuccessful because of the reality that funds paid are often funds spent, criminal prosecution for fraud can be the most effective deterrent of frauds to come.

In the absence of systematic checks to identify, protect against, and prosecute fraudulent claims, fraud can significantly increase the cost and complexity of response and recovery. The federal response to Hurricane Katrina, which was plagued by rampant fraud in claims for disaster assistance through the Federal Emergency Management Agency (FEMA), is especially illustrative. However, by building systematic checks into place to identify fraud, protect against it, and prosecute claims on the heels of loss, vulnerability

A survivor of Hurricane Irene in Lambertville, New Jersey, appears hesitant to speak to Patricia Selby (right), a Federal Emergency Management Agency community relations specialist visiting her home on September 15, 2011, because homeowners are especially vulnerable to fraud in areas struck by disasters. The inevitable tension between expediting recovery efforts and ensuring the legitimate use of resources makes response and recovery ideally suited to fraud, such as false disaster claims, unauthorized responders, and stolen funds.

to fraud can be substantially reduced in pursuit of more effective response and recovery.

Freshwater Demands and Shortages

Water covers about 70 percent of Earth's surface, and its interaction with the radiation from the sun is a major driver of climate events and the hydrological cycle, which continually recycles freshwater through evapotranspiration, condensation, and precipitation. Roughly 332,500,000 cubic miles of water are present in the oceans, land surface, and atmosphere—an amount that, for all practical purposes, can be considered constant. Of the total amount of water on Earth, only about 2.5 percent is freshwater. Generally characterized by having low concentration of dissolved salts and other total dissolved solids, freshwater is a naturally occurring resource and manifests on the Earth's surface. Rivers and lakes, the major source of humans' daily water for consumption and irrigation, constitutes approximately 22,300 cubic miles, approximately 0.007 percent of total water. Studies have shown that the oceans, seas, lakes, and rivers provide nearly 90 percent of the moisture in our atmosphere via evaporation, with the remaining 10 percent contributed by plant transpiration. One estimate of the volume of water in the atmosphere at any one time is about 3,100 cubic miles.

There is a constant amount of freshwater available, unevenly distributed across the planet (Table 1). Natural changes in the Earth's surface through history have dramatically changed the climate system many times, favoring water availability for some places more than others. In the present, Brazil, Canada, and Russia are the countries with the highest water availability and thus water security. The largest known aquifer in the world, Guarani Aquifer, sits underneath Brazil, Paraguay, Uruguay, and Argentina. The Guarani Aquifer coincides with the largest rainforest in the world, the Amazon forest, which experienced heavy deforestation between 1990 and 2004. Such practices alter the land cover characteristics, generating excessive runoff that erodes the soil surface, and substitute natural nutrient-replenishing processes with chemical fertilizers that damage the land and threaten the underlying water body's integrity and capacity.

The Earth's climate system is intrinsically related to the hydrological cycle; in fact, they are one and the same. Light from the sun travels through space until it reaches Earth; the atmosphere scatters or absorbs a portion of the energy and the rest makes it to the surface, then gets absorbed or reflected in different ratios depending on the surface properties. Oceans, which cover approximately 70 percent of the Earth's surface, absorb more radiation than land but have a faster heat exchange rate. The differences in reflectivity and energy-exchange properties of the land, ocean, and atmosphere create a potential difference that drives convective currents that stir the atmosphere and create winds that move clouds full of freshwater, naturally desalinated through evaporation with the energy absorbed by the oceans from the sun, inland, and when the right conditions are met, clouds pour out their content in the form of precipitation or snow. Snow piles up, storing freshwater in the form of glaciers, predominantly on high-latitude lands and elevated peaks. Rainwater falls on the surface and is absorbed by the soil, creating underground streams through porous strata. After complete saturation of the soil, water flows through the surface and accumulates in depressions, forming surface water bodies like lakes and ponds. Plants and animals benefit greatly from surface water bodies being such natural storage features—this is where most of their freshwater is withdrawn. Water flows slowly carve channels that connect inland water bodies to the ocean, closing the cycle where it began.

Technological advances in the 20th century were possible thanks to the burning of fossil fuels. Coal, natural gas, and petroleum are what remain of decomposed organic matter from millions of years ago, trapped between layers of soil at high pressures. When released from deep within the ground and burned, they produce energy, carbon dioxide, and water vapor. Energy is used to power most everyday tools and appliances, lights cities at night, and enables transportation, mass manufacturing, and construction of infrastructure. The major issues with the combustion of fossil fuels lie in carbon dioxide emissions, which, scientists all over the world agree, are unquestionably changing the chemistry of the planet's atmosphere. The effect of a changing atmosphere composition alters the Earth's energy budget and climate system. Changes in the climate system manifest themselves in local weather generally as geographical and seasonal displacement in the normal local climate. Droughts for regularly wet regions, shrinkage of mountain glaciers, an increased melting rate in Greenland and polar ice caps, stronger hurricanes off season, and a staggering number of species in danger of extinction are evidence of a dramatic change with the potential to threaten human life.

Limited availability of freshwater, increasing population growth and industrialization, excessive pollution from anthropogenic emissions, and poor management of water resources and land use of watersheds has created a world freshwater crisis. In 2002, 1.1 billion people had no access to safe water supplies and 2.4 billion had no sewer or sanitation facilities. The total population of the world in 2002 was 6.2 billion. Human deaths associated with lack of clean drinking water are estimated in millions per year. Likewise, biodiversity is being threatened. Estimates suggest that 10,000–20,000 freshwater species are extinct or at risk and more than half of the world's wetlands have disappeared.

Meeting Demand

In general, agriculture consumes most of the available water, followed by the industrial and domestic sectors. It is estimated that 69 percent of worldwide water use is for irrigation, with 15 to 35 percent of irrigation withdrawals being unsustainable. It takes around 792 gallons (3,000 liters) of water, converted from liquid to vapor, to produce enough food to satisfy one person's daily dietary need. Automated irrigation systems provide the water that crops need to grow. Excess water mixes with the chemicals used and percolates through the ground, contaminating underground bodies of water and drying the soil. Eventually, soil erosion decreases productivity until agriculture is no longer feasible.

Water consumption by the industrial sector is estimated to be around 22 percent worldwide. All industrial processes require water at some point for production of goods, cooling processes, and sanitation purposes. Major industrial users include power plants, which use water for cooling; refineries, which use water in chemical processes; and manufacturing plants, which use water as a solvent. For example, the construction industry requires extensive use of clean water when building concrete structures. Concrete is a mixture of cement, aggregate, and water mixed together in different ratios, depending on desired resistance properties of the element bearing the load. Impurities in water used, especially organic material, can affect negatively the resistance of the element. Water withdrawal can be very high for certain industries, but consumption is generally much lower than that of agriculture.

It is estimated that 8 percent of worldwide water use is for household purposes. These include drinking water, bathing, cooking, sanitation, and gardening. Basic household water requirements have been estimated at around 13 gallons per person per day, excluding water for gardens.

To meet demand, governments around the world had subsidized approximately 45,000 dams over 15 meters high by 2010. Dams are massive

Table 1 Total renewable freshwater supply by country

Region	Maximum annual renewable water resources (km³/yr.)	Country	Minimum annual renewable water resources (km³/yr.)	Country	Total (km³/yr.)
Africa	1,283	Congo, Democratic Republic (formerly Zaire)	.03	Cape Verde, Djibouti	5,580
North and Central America	3,300	Canada	0.02	St. Kitts and Nevis	7,621
South America	8,233	Brazil	122.00	Suriname	17,140
Asia	2,838	Indonesia	0.02	Kuwait	14,710
Europe	389	Norway	0.07	Malta	2,943
Former Soviet Union	4,498	Russia	7.80	Armenia	5,577
Oceania	801	Papua New Guinea	28.55	Fiji	1,607

Source: U.S. Environmental Protection Agency

hydraulic structures located at a narrow downstream exit out of a watershed. They are used to control the flow of water through a river or stream and to create large artificial reservoirs to provide water for irrigation and human consumption and to avoid flooding of cropland and human settlements. Another benefit of dams is the capability to produce low-emission hydropower. Hoover Dam, constructed in Nevada between 1931 and 1936 during the Great Depression, blocks the Colorado River and is capable of producing 4.2 billion KWh of electricity to supply Nevada and California. Unfortunately, dams also effectively destroy the surrounding ecosystem and regional water distribution. Low flow velocities in the reservoir are generally regarded as negligible for all practical reasons and are related to low dissolved oxygen levels in the still water. Decreasing oxygen levels in water reduce life expectancy of aquatic organisms, affecting the food chain.

Water demand already exceeds supply in many parts of the world, and as the population continues to rise, so does the water demand. Changes in water demand are intrinsically related to freshwater availability, population density, and economic power. Freshwater is viewed as a commodity in many parts of the planet. Because of failure to account for environmental impacts effectively, building huge infrastructure to control water becomes highly economically feasible.

Associated Shortages

The total quantity of water into any surface water system at any given time and the proportion of water lost are dependent on many factors, such as precipitation within its watershed; storage capacity in lakes, wetlands, and artificial reservoirs; the permeability of the soil beneath these storage bodies; the runoff characteristics of the land in the watershed; the timing of the precipitation; and local evaporation rates. Because of human intervention, the world's supply of freshwater, thought to be a renewable resource, is steadily decreasing. Pollution and mismanagement of resources faster than the natural cycle can replenish them have forced some ecosystems to change drastically.

The Aral Sea is an example of one of the world's worst environmental disasters. Located within the former Soviet Union, the Aral Sea was the fourth-largest lake on the planet, covering an area of approximately 26,300 square miles. From the 1960s, the rivers that fed the Aral Sea were diverted by Soviet irrigation projects, mainly to produce cotton. Reduced water input to the system gradually shrank the lake, changing the local microclimate and increasing temperatures

Table 2 Number of dams by region

Continent/country	Number of dams
Africa	1,269
Europe	4,277
South America	979
Central/Eastern Europe	1,203
North/Central America and the Caribbean	8,010
Asia and the Middle East	31,340
Oceania	577
Earth	47,655

and evaporation rates. As a result, the Aral Sea divided into two separate lakes, north and south. In 2005, the south lake was surveyed, and its area was calculated at 1,350 square miles. The north side area measured 1,270 square miles in 2008. Other than the environmental cost of losing 90 percent of the lake's surface area, transportation routes were lost and economic debacle followed.

Although a dam was built and completed in 2005 and water levels have risen 79 feet, in reference to lowest levels in 2007, the possibility of returning the Aral Sea to its original state is uncertain. The hydrological cycle will eventually replenish the lake, but the process is a slow one and changes in the surface properties and regional microclimate have the potential to alter the system's capacity to store water. Pollution and mismanagement of land and water resources threaten an already limited supply of freshwater. Growing populations and improving lifestyles in developing countries increase competition for water worldwide. At the same time, human-induced climate change disrupts typical weather patterns, offsetting seasonal variations in temperature and precipitation distribution. These factors add up to produce a net global decrease or shortage in freshwater availability.

Water Rights

Energy production, agriculture, manufacturing, and most services are all activities that require massive amounts of water. Most of the time, water being used in such processes is freshwater that ends up contaminated and dumped irresponsibly because of flexible environmental law. Sources for contamination may be thermal, chemical, or biological, altering the water's composition, causing an adverse effect on nearby ecosystems and introducing harmful pollutants into the food chain. To prevent such degradation of water bodies, mainly individual countries regulate water. In addition, international sets of rules have been proposed to safeguard this precious resource. The Helsinki Rules on the Uses of the Waters of International Rivers and the Hague Declaration on Water Security in the 21st Century are examples of such international regulations.

Water law is controversial in some parts of the world where a growing population faces increasing competition over a limited natural supply. Disputes over control of freshwater supply have taken place in many countries around the globe, many escalating to violence and bloodshed. One of the most notorious water wars in history took place in the state of California. As Los Angeles grew in the late 1800s, it started to outgrow its water supply. The city decided to outsource its water demand to Owens Lake, 223 miles away in eastern California. A couple of years after the construction of the aqueduct, the lake's water level lowered and started making agriculture difficult for surrounding farmers. This led to the farmers trying to destroy the aqueduct in 1924. Eventually, Los Angeles prevailed and kept the water flowing. By 1926, Owens Lake at the bottom of Owens Valley was completely dry because of water diversion. By 1928, Los Angeles owned 90 percent of the water in Owens Valley. Agriculture in the valley was effectively dead.

In the United States, the Clean Water Act (CWA) of 1972 is the primary federal law governing water pollution. The law establishes the basic structure for regulating discharges of pollutants into the waters of the United States and regulating quality standards for surface waters. Under the CWA, the U.S. Environmental Protection Agency (EPA) has implemented pollution control programs, such as setting wastewater standards for industry. Many developed countries have adopted similar regulatory laws to protect and conserve their water systems.

Because it is expensive to implement environmental laws, underdeveloped nations many times lack the resources to effectively protect their water systems. Lack of environmental regulations, cheap labor, lower taxes for companies, and abundant natural resources in poor nations attract foreign investments seeking lower operational costs and higher profits. Goods are manufactured using local resources to be later exported to consuming nations. Water is privatized and consumed irresponsibly, leaving poor countries through trade in the global market.

Given the fact that water access is a cross-border source of concern and potential conflict in the Middle East, the eastern Mediterranean, and parts of North America, among other places, some nongovernmental organizations (NGOs) and scholars argue that the right to water also has a transnational or extraterritorial aspect. They argue that given the fact that water supplies naturally overlap borders, states also have a legal obligation not to act in a way that might have a negative effect on the enjoyment of human rights in other states.

In 2002, the right to water was recognized through the International Covenant on Economic, Social and Cultural Rights (ICESCR). The committee of experts agreed on the fact that "The human right to water entitles everyone to sufficient, safe, acceptable, physically accessible and affordable water for personal and domestic uses. An adequate amount of safe water is necessary to prevent death from dehydration, to reduce the risk of water-related disease and to provide for consumption, cooking, personal and domestic hygienic requirements." Following its publication, several European nations agreed and formally acknowledged the right to water to be part of their treaty obligations under the ICESCR. Eventually, in 2010, the UN Human Rights Council adopted a resolution recognizing that the human right to water and sanitation are a part of the right to an adequate standard of living.

A water distribution point in El Mina, about a mile west of the town center of Nouakchott, Mauritania, October 2010. UNICEF Mauritania works to increase the supply of household drinking water and stabilize water prices at affordable levels.

Water Crisis

The International Water Management Institute (IWMI) in 2007 conducted a study to see if the world had sufficient water to provide food for its growing population. It assessed the current availability of water for agriculture on a global scale and mapped locations suffering from water scarcity. It found that a fifth of the world's people—more than 1.2 billion—live in areas of physical water scarcity, where there is not enough water to meet all demands. One-third of the world's population does not have access to clean drinking water, which is more than 2.3 billion people. A further 1.6 billion people live in areas experiencing economic water scarcity, where the lack of investment in water or insufficient human capacity makes it impossible for authorities to satisfy the demand for water. To avoid a global water crisis, farmers will have to strive to increase productivity to meet growing demands for food, while industry and cities find ways to use water more efficiently. It has been proposed that when annual per capita renewable freshwater availability is less than 1,700 cubic meters, countries begin to experience periodic or regular water stress. Below 1,000 cubic meters, water scarcity begins to hamper economic development and human health and well-being.

Considering also the current energy limitations, most countries rely only on their surface water and groundwater resources, which are exploited at a faster rate than the system can replenish. Energy demand for pumping water rises as fuel prices go up because of conflicts in oil-producing countries and shortening of supply. As the world supply of oil reaches a peak, trying to keep up with increasing energy demand, energy-dependent water supplies will have to be managed, their increased cost increasing fares, directly affecting consumption by low-income families.

Currently, new technologies are being developed to counteract water shortages. One of them is desalination, which is currently expensive compared to most alternative sources of water. Nevertheless, desalination plants have been used extensively in Persian Gulf countries rich in oil.

Coping with water crisis is a global endeavor. Planning urbanization to sustain geographically expanding populations and booming economies in a sustainable manner needs to be seriously considered if the right to water for all is the goal. Reducing demand through more efficient use, protection, and conservation of water resources is considered by many as the responsible and most cost-effective way to ensure water security. In agriculture, the use of high-efficiency irrigation techniques, use of plastic liners in irrigation canals to prevent leaks, level fields to reduce runoff, choosing crops appropriate for the climate, and eliminating government subsidies of inappropriate crops or methods can greatly reduce the sector's water demand. Individuals can also reduce their water footprint by installing low-flow faucets and appliances, replacing lawns with native vegetation, or watering their lawns at night to reduce water loss resulting from the higher daytime evaporation rate. Industry and municipalities can shift to processes that save water, invest in repairing pipe leaks, and recycle "gray" wastewater. Governments can adopt economic approaches to conserve water by stopping government subsidies and inefficient practices, setting water price standards that reflect environmental costs, and decentralizing control over water.

Fusion Center

Fusion centers are sometimes described as intelligence or information sharing centers. A fusion center is a key mechanism designed to exchange information and intelligence at the local, state, and federal levels. A fusion center is not a monitoring or operational center, nor does it respond to 911 calls or other direct interactions with the public. Instead, it is a physical location for information analysis. The main role of a fusion center is information collaboration and coordination of the fusion process in order to alert law enforcement agencies concerning threats and criminal activities prior to an actual event. The structure of fusion centers allows all levels of law enforcement agencies to use an improved information or intelligence sharing and dissemination system that maximizes the prevention, protection, and response capabilities of law enforcement agencies throughout the country.

Development of Fusion Centers

The development of the fusion center movement began with socioeconomic and technological changes in the United States during the 1960s and 1970s. New conjunctures and improvements had forced law enforcement agencies to carry out new approaches and solutions in pursuit of improved service. Some law enforcement agencies accordingly established local information sharing system units that have operated for decades. However, the tragic terrorist attacks on September 11, 2011, showed that there was a critical gap in information and intelligence sharing among all levels of law enforcement agencies throughout the country. This crisis highlighted a crucial need to refocus information sharing strategies in terms of a unified and collaborative operative response to acts of terrorism, and accordingly the need for a formalized information repository and sharing center.

Following September 11, the term *fusion* has come out of a new concept defined as a facilitating and embracing process for information sharing and intelligence through all levels of government agencies, as well as the public and private sectors. The expansion of this new fusion center philosophy has provided a more cooperative approach to law enforcement agencies within the United States. Fusion centers have been established, organized, and managed by state and local entities within their respective missions. The Department of Homeland Security (DHS) has supported the fusion center movement, providing training, grants, and staff. Specifically, after Congress passed the 9/11 Commission Act in 2007, fusion centers have been promised to be developed by DHS, becoming an important component of homeland security strategy within the United States.

Fusion Process and Function

The fusion process represents a new intelligence function among local, state, and federal law enforcement agencies. Data fusion is a technique that exchanges and combines information and intelligence from multiple sources in order to improve accuracy. It is expected that an individual or user will turn raw information into more comprehendible and usable knowledge by analyzing and putting together the small parts that enable agencies to see a more comprehensive picture of crime, security, and terrorism issues. Thus, this collaborative effort prevents disorganization, duplication of effort by multiple agencies, and agencies working at cross-purposes.

The fundamental purpose of creating fusion centers is to combine multiple information- and intelligence-gathering services into a single center that provides a unique portal for analysis. This collaborative effort maximizes agencies' abilities to respond to terrorist threats and other criminal activities by analyzing data from various sources. This improved and proactive information is disseminated among federal government agencies and their state, local, and tribal counterparts, representing an advanced information flow between local entities and federal authorities.

Contrary to similar agencies organized pre-9/11, such as the Regional Intelligence Center (RIC) and the High-Intensity Drug Trafficking Area (HIDTA), whose purpose was to identify and prevent drug traffickers in their efforts, these new-generation fusion centers provide a broad range of data to law enforcement agencies. The function of a fusion center allows government, public safety, and private sectors to come together for a common goal that enhances information and intelligence sharing. Local, tribal, state, and federal law enforcement agencies play an active role in accumulating information during the fusion process. Non–law enforcement agencies, such as private-sector organizations and public safety entities, are also rich intelligence sources that provide significant information, such as suspicious activity reports. The information provided by non–law enforcement agencies is therefore also an important component in obtaining meaningful and actionable information for analysis by law enforcement personnel.

Ideally, fusion centers consist of representatives who are analysts performing strategic duties from different local, state, and federal law enforcement agencies. Each agency representative is responsible for detecting and preventing threats and criminal attempts by analyzing and evaluating information. Representatives also determine what type of information is needed by these agencies. Received information such as incident reports from local police officers or first responders, intelligence reports from various agencies, and reports of suspicious activities from public safety organizations are collected within the system. Following the fusion process, analyzed reports are disseminated to related agencies as intelligence assessments, alerts, bulletins, and strategic reports. An improved situational awareness is provided throughout the country, and these consolidated reports allow law enforcement agencies to see trends and patterns in the "big picture" related to homeland security issues.

G

Global Food Crisis

The phenomenon of a global food crisis, marked by simultaneous disruptions to food accessibility in multiple regions globally, is a relatively recent event.

Local Risk, Local Response

The potential for food shortage is an inherent risk in any agricultural system given the unpredictable impact of weather, crop success, political dynamics, and other factors. These local roots have made famines largely local affairs for most of history. The Great Famine of 1847, for example, was largely limited to Ireland, and the famine associated with Chairman Mao's Great Leap Forward in the 1950s affected Chinese peasants.

The localized nature of these crises was reflected in the first wave of policy responses. The United Nations formed the World Food Programme (WFP) in 1961, with a mandate to provide food both during and in the immediate aftermath of emergencies. The organization is the only unit working under the umbrella of the United Nations with this as its sole objective. The WFP relies for its work on a combination of donated cash and food from governments as well as a network of thousands of employees and contractors, 90 percent of whom work in the field rather than at the agency's Rome headquarters.

The work of the WFP complements that of its older sibling, the Food and Agriculture Organization of the United Nations (FAO). Whereas the WFP was created to address immediate humanitarian concerns, the FAO was organized to promote longer-term food security and nutrition at the local level. The agency has since become a centralized platform for gathering data, sharing agricultural research, and dispersing expertise and resources into the field in country-level projects around the world.

These efforts bolstered national crisis responses. In many countries of the Southern Hemisphere, the state-led development paradigm adopted by former colonies in their first decades of independence emphasized self-sufficiency rather than global trade. The resulting policies focused on import substitution through a combination of the nurturing of national champions and welfare policies oriented to the stabilization of local prices and production. During this period, many commodity-producing countries created marketing boards that acted as para-statal organizations that helped support price stability for both farmers and consumers and often combined this role with the creation of strategic grain reserves for emergency response.

The Global Food Crisis From 1972 to 1973

The pattern of generally localized crisis was altered significantly in the early 1970s. The global food crisis of the 1970s had its roots in a global weather pattern that disrupted grain production across the rice-producing countries of southeast Asia in 1972 and later across the wheat- and corn-farming areas of the Northern Hemisphere. The resulting decrease in production significantly reduced global grain availability, leading to an inevitable increase in prices. Rising prices in turn interacted with instability in financial markets following Richard Nixon's decision to take the U.S. dollar off the gold standard and were cited as a factor by the Organization of Petroleum Exporting Countries (OPEC) in support of its 1973 decision to raise oil prices.

Although the initial crisis appeared to end in 1973, in practice many parts of the world were affected through the 1970s because of a combination of global inflation and local weather and other dynamics. The depth of the crisis led the FAO to convene the World Food Conference in 1974 to develop a global policy framework for crisis response and managing food security. Within the FAO, the conference resulted in the creation in 1975 of the Global Information and Early Warning Service (GIEWS), a global network of monitoring and data-gathering efforts targeted at identifying potential emerging crises and providing local information necessary for effective crisis response. The GIEWS remains central to the FAO's work with food insecure countries and is housed within its Emergency Coordination Group.

The conference also led to the creation of the International Fund for Agricultural Development (IFAD) in 1977. The IFAD is an independent agency within the United Nations group, with a mission of eliminating rural poverty by promoting food security and better nutrition. Like its peers the WFP and the FAO, the IFAD has a central bureaucracy but develops and implements programs at the country level.

The World Bank and Agriculture

The World Bank also stepped into the global debate about food policy with its 1982 World Development Report. These annual documents serve to define the Bank's lending agenda for the coming year and are thus used as a barometer of the Bank's priorities. The 1982 report included the Bank's response to the global recession that began in 1981 as well as its proposals for the role of agriculture in development. The document signaled a commitment to funding agricultural research as well as a commitment to promoting market-centric policies that later became known as the "Washington consensus."

These policies had a direct impact on many of the less-developed countries that relied on World Bank funding, especially those in Africa. In many cases, the Bank's preference for private-sector solutions led to reductions in the role of marketing boards as well as reductions in government subsidies for seed, fertilizer, and other inputs, all under the assumption that global prices would provide better signals to guide production in the absence of local distortions. Simultaneously, the bank neglected to follow through on its funding commitments for agricultural research, which fell from 16 percent of aid to African countries in 1982 to 4 percent in 2006. This decline was echoed by a widespread lack of foreign direct investment from the private sector. The end result was a steep decline in agricultural output in Africa from the early 1980s to the middle of the 2000s, leaving many on the continent significantly exposed to global commodity prices.

The Crisis of 2007

Unlike the 1972–73 crisis, the rapid onset of the food crisis that began in 2007 was not marked by significant declines in production (though poor wheat harvests in 2007 did play a role). Although global grain stocks relative to use had been declining steadily since the late 1990s, leading to a steady increase in nominal prices, the rate of decline did not accelerate commensurately with the sudden spike in food prices. Although precise attribution remains a point of contention, a consensus in the literature has developed around a "perfect storm" combination of a range of factors, including the increasing diversion of food crops to biofuel, rising oil prices (which increase both fertilizer and transportation costs), and the declining U.S. dollar. In the case of rice, many Asian countries reacted to potential disruptions to the staple food by enacting emergency policies ranging from export bans in rice-producing countries such as Thailand and massive purchases by importing countries seeking to secure supply. Perhaps the most controversial claim about the crisis involves the role of financial speculators, whose involvement with first the oil and later the wheat futures markets was found by the U.S. Senate to have contributed to price spikes in each case. Estimates by the World Bank and other agencies found that as many as 100 million people globally were pushed into poverty by the resulting crisis.

Given the severity and duration of the global crisis that began in 2007, both the traditional food security agencies as well as new entrants have begun to blend work on crisis response with preventive measures to lower global vulnerability to food price instability in the future. This blend was reflected in the approach of the World Bank, which made agriculture the central topic of its 2008 World Development Report (titled "Agriculture for Development") for the first time since the 1982 report. It also introduced its Global Food Crisis Response Program (GFRP) in that year. The program brings together the Bank's capabilities for emergency lending and grants for food relief under one umbrella organization. Importantly, the program combines this capability with a commitment to making investments in agricultural research in order to build food security capacity at the country level. The GFRP budget was raised to $2 billion in 2009 and has remained at that level following the second spike in food prices in 2010.

The various elements of the United Nations system that work in areas touching on food security have also moved toward a more explicit emphasis on the blend of crisis response and longer-term development. Members of the system have undertaken a number of planning meetings since 2008 geared toward producing greater cooperation across agencies. Among the more concrete outcomes of these meetings is a set of guidelines issued in 2009 intended to guide more structured collaboration between the FAO, the IFAD, and the WFP in order to take advantage of their global resources and complementary expertise.

The food crisis has also prompted a response from the private sector, particularly from the Bill and Melinda Gates Foundation, which has made investments in global food security one of its top priorities. The foundation's mission includes three primary programs, of which Global Development is the second largest (after its more widely publicized Global Health efforts). In 2010 alone, the foundation made $242 million in grants for global agriculture, focused largely on boosting the ability of smallhold farmers to access markets, boost yields, and support local food security.

Global Warming

Global warming is one of the environmental crises of the 21st century. Global warming refers to the rising of the average temperature of the Earth's atmosphere. The origin of global warming dates back to 1896, when Svante Arrhenius, a Swedish chemist, developed the theory that burning of fossil fuels such as coal, oil, and natural gas emits carbon dioxides, which produce excess heat that is trapped in Earth's atmosphere, causing a rise in global temperature. Arrhenius explained his theory of global warming by the process of the "greenhouse effect," which was first observed and posited by Joseph Fourier in 1824. This article explains the concept of global warming, and its origin, causes, effects, and trends. It also describes the vulnerable groups, the responses to global warming, and measures to curb it. Global warming is expected to bring developmental, human, and environmental crises. The theme is more relevant in the context of crisis management.

Causes of Global Warming

Earth's atmospheric temperature rise results from increasing concentration of greenhouse gases (GHGs) such as water vapor, carbon dioxide, methane, ozone, nitrous oxides, and chlorofluorocarbons (CFCs). The greenhouse gases are produced mainly by human (anthropogenic) activities such as burning of fossil fuels, deforestation, and transportation. Fossil fuels dominate the global energy regime and account for over 85 percent of the total global energy consumption.

There is scientific consensus that the global warming is the result of human-induced GHGs emissions. The Fourth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC) estimates that carbon dioxides from fossil fuel burning account for about 57 percent, and another 17 percent result from deforestation and biomass decay and together with other sources, carbon dioxides account for about 77 percent of the total GHG emissions. The other major greenhouse gasses are methane (14 percent), nitrous oxides (8 percent), and other gases (1 percent). Rapid industrialization, urbanization, and the increase in number of vehicles on the roads have contributed substantially to carbon dioxide emissions. Methane, the second potential GHG, is released from landfills and rice fields when bacteria break down organic matters. Clathrates—the frozen ice masses—are also sources of methane that lie at the bottom of the Arctic sea beds. Methane is released when ice melts as a result of the rise of temperature of ocean water. Nitrous oxide is released from chemical fertilizers, pesticides, and gases used in various industrial processes. Different greenhouse gases have different heat-trapping potentials. Methane has 20 times more warming effects than carbon dioxide. Nitrous oxide has 300 times more warming potential than carbon dioxide.

Disagreements have arisen, however, regarding the nature, causes, and consequences of global warming. Some scientists disagree that the causes of global warming are based in human factors, and they argue that it is the result of natural fluctuations in the Earth's temperature and changing climate system cycle. Others view global warming as caused by variability in solar radiation and they argue that the temperature increase over the past century is the result of intense solar activity and varying solar radiation. Studies also show that fossil fuels produce air pollutants that make the clouds reflect more of the sun's rays back into space by a phenomenon known as "global dimming." Addressing global dimming may cause more global warming, as well as other environmental problems.

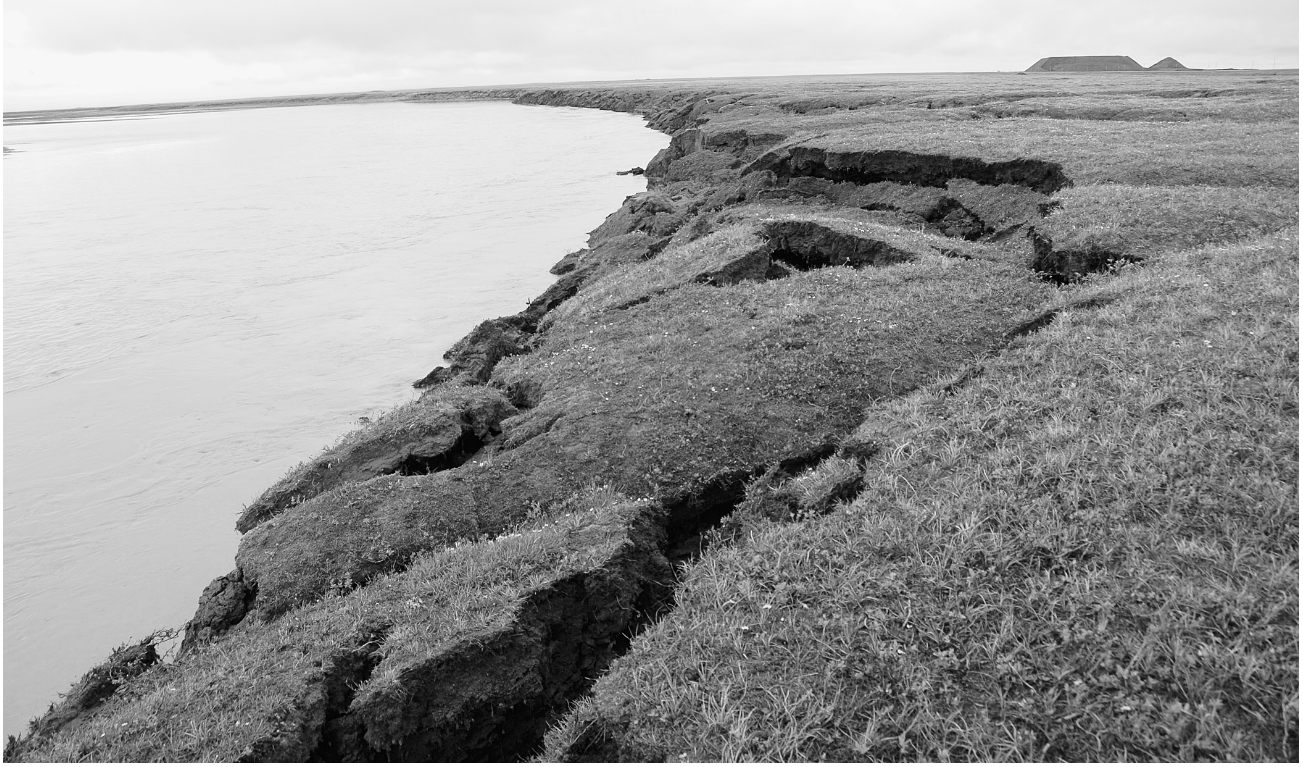
Trends in Global Warming

Scientists view that the global warming trends recorded throughout the 20th century are extreme and atypical. The Fourth Assessment Report of the IPCC indicates the world average temperature has increased by approximately 0.6 degrees C and two-thirds of warming occurred since 1975. Of the 12 warmest years since 1850, 11 were between 1995 and 2006. The IPCC indicates that in the present century, the global surface temperature is likely to rise a minimum of 1.1 to 2.9 degrees C (2.0 to 5.2 degrees F) and to a highest scenario of 2.4 to 6.4 degrees C (4.3 to 11.5 degrees F).

Effects of Global Warming

The global warming is causing melting of ice and other cryospheric changes. Greenland's ice sheets are most vulnerable to global warming. Rising sea level, as a result of thermal expansion of the ocean and melting of ice because of global warming, is inevitable. The IPCC's Fourth Assessment Report estimates that global average sea level has risen since 1961 at an average of 1.8 mm/year and since 1993 at 3.1 mm/year. The report predicts a sea level rise between 0.18 and 0.59 meters by the end of the present century. An increase in global temperature may bring changes in temperature and precipitation patterns that may increase the frequency, duration, and intensity of extreme weather events such as droughts, floods, heat waves, and windstorms. Flooding, the most common event, is predicted to increase in its intensity.

Global warming and consequent sea level rise are expected to cause coastal erosion and loss of biodiversity, severely affecting food security systems, causing problems of malnutrition and hunger, and aggravating already existing environmental and human crises. Human migration and displacement with environmental refugees are expected to increase. Global warming and extreme climate



Large chunks of soil collapse as a result of permafrost thaw and erosion along the Sagavanirktok River on the north slope of Alaska near Deadhorse in July 2009. When permafrost thaws, microbes digest vegetation, which results in the release of methane, a potential greehouse gas that is thought to lead to global warming. Methane can also be released into the atmosphere through another process of thawing: The rise of ocean water temperatures can thaw frozen ice masses at the bottom of Arctic sea beds.

events have potential impacts on water and energy resources, as well as other sectors such as agriculture, forestry, and fisheries. The resulting human and environmental crises, coupled with resource scarcity (food, water, and energy) arising from global warming, may generate political conflicts.

Global warming may cause shifting in temperature regimes, changes in crop yields, and extinction of species. Severe human health problems are likely to occur because of increases in infectious diseases spread by pests and insects. Vector-borne diseases such as malaria, cholera, fileria, and yellow and dengue fevers are expected to rise because of global warming and climate change. Diarrheal diseases associated with floods and droughts are likely to increase. Global warming is expected to put stress on water resources, energy supply, and other economic and ecological systems. Global warming is likely to affect certain ecosystems more than others, for example, tundra, mangroves, and coral reefs. Species and their habitats are decreasing, and the chances of ecosystems to adapt naturally and conditions of equilibrium are also diminishing. Rising temperatures may increase evaporation and water loss, causing reductions in water supplies, leading to water crisis. Nearly 1.8 billion people could be living in water-scarce environments by 2080. The consensus among many scientists is that human-induced global warming will dramatically increase extreme weather conditions that will destabilize the economy and the environment. Growing intensity of climate change events such as hurricanes, floods, and droughts is expected to seriously undermine development.

The ocean is a huge "carbon sink," holding about 50 times as much carbon as the atmosphere. The carbon sink potential of the ocean, however, is diminishing because of global warming. As a result of increased thermal stratification of oceans, there have been substantial reductions in phytoplankton, which store carbon dioxides. Increased atmospheric carbon dioxide is also causing an acidification of the ocean, affecting marine organisms, especially the shell-forming organisms. Studies suggests that the amount of oxygen dissolved in the oceans may decline by global warming, with an adverse impact on marine life. Scientists, however, argue several positive impacts of global warming, for example, a longer growing season, higher-yield harvests and increased food production, better human health, and a decrease in climate-related disasters. Although global warming is a major threat to coral reefs, studies reveal that some coral species may be able to adapt to warmer oceans. The impacts of global warming and climate change, however, remain uncertain.

Vulnerable Groups

Vulnerability to global warming and consequent climate change events is expected to increase. Small island states are the most vulnerable group, facing the greatest risks to global warming, sea level rise, coastal flooding, and the other extreme weather events. Sea level rise is expected to exacerbate inundation, storm surge, marine erosion, and other coastal hazards in small island states. Global warming and extreme weather events are likely to reduce water resources in these countries. Children, women, the elderly, and communities living in poverty are particularly the groups most vulnerable to global warming and climate change.

Responses to Global Warming

In 1988, the United Nations Environment Programme and the World Meteorological Organization established the Intergovernmental Panel on Climate Change (IPCC) to assess the scientific knowledge on global warming. The United Nations Framework Convention on Climate Change (UNFCCC), an international environmental treaty agreed at the Rio Earth Summit in 1992, adopted a range of policies to prevent dangerous human-induced greenhouse gases causing global warming. The Kyoto Protocol to the UNFCCC, adopted in December 1997 and entered into force in February 2005, aimed at reduction of greenhouse gases to combat global warming.

Measures to Curb Global Warming

Global warming and climate change are imminent. Action must be taken to curb further buildup of heat-trapping gases in the atmosphere. There is a need to modernize power plants, reduce dependence on fossil fuels, generate electricity from nonpolluting sources, expand clean energy sources, and increase energy efficiency. All mitigation strategies need to be intensified in reducing the GHG emissions, enhancing the capacity of carbon sinks and for a low carbon development. The strategies of low carbon development can be taken by investing in clean energy sources and promoting "green growth" and "green development." Strict enforcement of environmental legislation and policies is crucial. Intensification of reforestation programs is vital in order to increase the carbon sink capacity of vegetations and reduce production of greenhouse gases.

Groupthink

Reaching consensus, the general agreement among all members of the group, is desirable in many contexts. Consensus should not occur, however, until after careful analysis and consideration of all relevant points of view. Realistically, absolute consensus is rarely achieved and, in some cases, can be catastrophic. The groupthink concept offers a clear characterization of perilous consensus.

In what has become a classic work, psychologist Irving Janis characterized the desperate drive for consensus at any cost as "groupthink." Janis's early work focused mainly on disastrous policy decisions made by groups who counseled United States presidents. Groupthink occurs when members of a decision-making group are so obsessed with reaching consensus that they discount evidence that challenges the prevailing ideas of the group. Scrutiny of the pros and cons of an idea is replaced by a sort of group arrogance that assumes the group will make the best decision without deliberation. Janis believed groupthink was at the source of such historic failures as Pearl Harbor, the Bay of Pigs invasion, and the Vietnam War.

Warning Signs of Groupthink

Janis provides six warning signs of groupthink:

- *Limited discussion:* The group limits discussion to just a few alternatives. These alternatives are usually the most comfortable choices available to the group.
- *Ignoring risk:* The group does not reevaluate its choices, even after new signs of risk become apparent.
- *Ignoring alternatives:* The group does not reevaluate its choices to see if it may have passed over an alternative that could provide even greater benefits.
- *Ignoring advice:* The group does not seek advice from relevant experts within the organization.
- *Limiting focus:* The group seeks facts and opinions that support its decision while ignoring information that does not.
- *Failure to plan for crisis:* The group fails to consider the potential consequences that might exist if its plans fail.

When these warning signs are present, groups are in danger of unequivocally supporting a counterproductive policy despite the availability of known alternatives.

Avoiding Groupthink

To avoid the potential dangers of groupthink, groups should carefully consider if consensus has come at the cost of productive conflict, accuracy, and efficiency. Productive conflict refers to the clash of opinions and the discussion of contradictory evidence. In this case, "clash" refers to healthy disagreement among group members. When a group allows productive clash, group members feel free to speak up if they disagree with a decision or potential decision. Without such productive clash, the group stops functioning as a unit. One or two individuals control the group, thereby negating the primary strength of groups—multiple perspectives. When group members choose to avoid productive clash, the quality of the group's decisions is in jeopardy.

To ensure that adequate clash exists, Carl Mann suggests group members answer four questions as part of their group deliberations:

- Is there enough evidence to warrant the conclusion?
- Is there negative evidence that rebuts the conclusion?
- Does the evidence genuinely support the conclusion?
- Does the conclusion go beyond the supporting materials?

An informed discussion that considers all points of view and carefully considers the quality of evidence available is likely to avoid making the types of seriously flawed policy decisions that continue to precipitate crises.

Recent Applications of Groupthink

More recently, some scholars have argued that groupthink contributed to the space shuttle *Challenger* disaster as well as the U.S intelligence agencies' assessment of Saddam Hussein's weapons of mass destruction efforts. To clarify, communication scholars Dennis Gouran, Randy Hirokawa, and Amy Martz found that managers from Morton Thiokol, a company responsible for producing key components of the space shuttle *Challenger*, initially recommended that the launch be canceled. They wanted to cancel the launch because they feared that the temperature was too low to allow the rockets to function properly. These managers perceived external pressure from the National Aeronautics and Space Administration (NASA) to reverse their decision to delay the launch. This perception by the engineers that they were being pressured to go along with what they believed was the group's consensus is a clear sign of groupthink. Unfortunately, this decision led to the explosion of *Challenger* 71 seconds into the launch. The shuttle exploded for precisely the reason that made the Morton Thiokol managers originally ask that the launch be delayed. Worse, Phillip Tompkins's study focusing on the space shuttle *Columbia* disaster nearly 10 years later found that some of the same group decision problems were still evident in NASA.

H

Hazard, Definition of

The origin of the English word *hazard* is considered to come from the old French word *hasard*, meaning a game of chance using dice; from the Spanish *azar*; from the Arabic *az-zahr*; from the Persian *zar*; or from the Turkish *zar.* The word indicates something causing danger, peril, risk, or difficulty. Hazard is used both as a noun and as a verb. As a noun, hazard means a game played with two dice, an earlier and more complicated form of craps. It is also used to refer to an obstacle, such as a bunker, sand trap, or the like on a golf course. As a verb, hazard means to offer (e.g., a statement or conjecture) with the possibility of facing criticism, disapproval, failure, or the like. It means to put to the risk of being lost or to expose to risk. Hazard and risk are often confused with regard to their meaning and implications. The term *hazard* has already been explained above; however, the term *risk* is derived from the classical Greek word *Rizikon*, which means root. Hazard has an existing situation, which is likely to cause damage or harm, whereas risk is an anticipated situation of potential harm or danger that can be avoided, prevented, or mitigated.

Definition of Hazard

According to terminology suggested by the United Nations International Strategy for Disaster Reduction (UNISDR) on disaster risk reduction in 2009, a hazard is defined as a dangerous phenomenon, substance, human activity, or condition that may cause loss of life, injury, or other health impacts; property damage; loss of livelihoods and services; social and economic disruption; or environmental damage. Such hazards arise from a variety of geological, meteorological, hydrological, oceanic, biological, and technological sources, sometimes acting in combination. In technical settings, hazards are described quantitatively by the likely frequency of occurrence of different intensities for different areas, as determined from historical data or scientific analysis.

Statistically, hazard is defined as the probability of occurrence of a potentially damaging event, process, activity, or condition of given characteristics in a given space and time. Besides the probability of occurrence, the characteristics of the hazard are described by its physical dimensions, including location, magnitude (mostly defined in terms of energy released), duration of occurrence and impact (the period), geographical extent, frequency (how often it occurs), intensity, timing of occurrence, and speed of onset (how fast or slowly it occurs). Hazard is not deemed to be synonymous with risk, although it is an important determinant of risk. Hazard is actually the potential to cause harm, whereas risk is the likelihood of harm in defined circumstances. The degree of risk depends upon the degree of exposure and vulnerability of the element exposed to a given hazard. A low exposure to something that is highly hazardous may result in a low risk, whereas a high exposure to something of low hazard may result in moderate or even high risk.

A widely accepted definition characterizes natural hazards as "those elements of the physical environment, harmful to human beings and caused by forces extraneous to him/her." The term *natural hazards* refers to all atmospheric, hydrologic, geologic, and wildfire phenomena that, because of their location, severity, and frequency, have the potential to affect humans, structures, and activities adversely. The probability of occurrence of hazards depends on certain causative factors and conditions that can be identified and assessed for disaster risk management. However, such hazard identification and assessment will have some uncertainty, which should be informed while expressing the results. The factors affecting the occurrence of hazards may be inherent or acquired.

Hazards and Human Involvement

The term *hazard* includes an element of human involvement. A physical event, such as an earthquake in the oceans or polar areas, that does not affect human beings is a natural phenomenon but not a hazard. A potentially damaging phenomenon that occurs in a populated region would be termed *probable hazard*. Similarly, a hazardous event that causes an unacceptably huge number of human deaths or colossal damages to economy and environment would be termed a *disaster*. In areas where there are no human interests, natural phenomena do not constitute hazards nor do they result in disasters. This definition is thus at odds with the perception of hazards as unavoidable havoc wreaked by the unrestrained forces of nature. It shifts the attention from natural phenomena or processes to the concurrent presence of human beings and natural events. Earlier, hazards were considered by a school of thought as natural occurrences and "acts of God," but the increasing awareness and understanding of hazards has now led to the view that the problem of hazards cannot be handled without considering humans' relationship with nature and the nature of human society.

When a particular hazard of given characteristics is considered for disaster risk assessment/reduction, it is termed a "specific hazard." In cases when more than two hazards are considered simultaneously in the risk management process, it is termed a "multi-hazard approach."

Cascading Hazards

Hazards may not occur in isolation from each other. Rather, it is quite possible that one hazardous event may trigger another hazardous event, followed by still another. This is termed "cascading hazard." For example, an earthquake in a hilly terrain may cause landslides, which may block the water channels, and the bursting of these landslide-dammed channels leads to flash floods in the area. Thus, a single hazard is likely to have multiple impacts. For instance, an earthquake damages buildings and infrastructures, associated landslides result in loss of land and crops, and the flash floods erode the structures/infrastructure and inundate the affected area.

Hazard Mitigation

Hazard mitigation can be broadly defined as measures directed at reducing risk or damage to property and lives from natural or human-made

Drainage tubes installed along Route 30 in Blenheim, New York, diverting water during a heavy rainstorm on November 23, 2011. The tubes were part of mitigation work that was completed after flooding struck the area during Hurricane Irene in August 2011. Hazard mitigation techniques, such as this structural example, can reduce the vulnerability of the property or life exposed to the hazard.

hazards. Suitable mitigation measures are determined by assessing which factors cause the most risk, and which of those will provide the most safety for cost. Hazard risk mitigation techniques can diminish the hazard and reduce the vulnerability of the property or life exposed to the hazard. Hazard mitigation techniques are structural (for example, dykes to protect from floods). Vulnerability mitigation techniques can be structural (for example, raising a home above flood level) and nonstructural (for example, regulation to address behavioral changes among the population with regard to the hazard). Mitigation is generally considered to be the first stage of disaster/crisis management. It allows for building community and personal resilience to hazards prior to the event through long-term investments in safety. This discussion focuses on nonstructural mitigation of natural hazards through incorporation of indigenous knowledge and local land use planning. The case study features the process of collaborative development of a risk-based land use guide for Metro Vancouver, British Columbia, Canada, with a goal of mitigating hazards and strengthening community safety through informed land use decisions.

Humans have been trying to mitigate hazards for centuries. Vincent Covello and Jeryl Mumpower suggested that virtually all great ancient civilizations (e.g., China, Maya, Egypt, and Mesopotamia) directly intervened to mitigate the effects of natural disasters and that governments have played a major role in developing and financing elaborate systems of flood control. Given the growing costs of disasters, public-private partnerships with the goal of mitigating hazards are gaining recognition as a potential way to share risk and costs of long-term investments in the resilience of communities and societies.

Researchers such as David Godschalk and colleagues in the United States and John Handmer

Case Study: Risk-Based Land Use Guide for Hazard Mitigation

Risk-based land use guides provide municipal staff with principles and tools to evaluate and recommend land use decisions that mitigate disasters. To be effective, the guides incorporate principles and tools recognized locally, nationally, and internationally as the most informed of our time (best practices). A land use guide targets municipal staff because they provide both the strategic and operational recommendations and decisions on land use for urban centers. Large urban centers, in general, are the most vulnerable land uses.

In recognition of the magnitude of responsibility that municipal staff carry in building safe communities, a consortium in southwest British Columbia, Canada, formed to assist municipal staff in consolidating informed risk-based land use practice into a practical guide. Its development is predicated on the inclusion of local and scientific informed practice. It is community focused, based on common economy, society (culture, governance), and geography. The southwest British Columbia example was driven by threats posed by its multihazard geography.

Hazard Context

Southwestern British Columbia faces challenges of a rugged mountainous, fiord-style coastal geography driven by tectonic plate convergence causing earthquakes and volcanoes. Prevailing onshore winds deflected by the mountains produce large amounts of precipitation, causing multiseasonal rapid-onset flooding. The volcanic mountains are unstable, being composed primarily of poorly consolidated fine-to-coarse fragments. The other mountains, of granitoids and metamorphosed sedimentary rock, are coated in debris from their own disintegration and material left by the retreat of continental glaciers at the end of the last ice age. These slopes regularly release debris flows and rock slides, often triggered by high rainfall events. The Fraser River, fed from the interior of British Columbia, has caused extensive valley flooding from rapid spring snowmelts. The region remains heavily forested, and fires and blowdowns threaten developments.

Vulnerability Context

Over 2.5 million people live on the Fraser River delta and along its mountain flanks (Metro Vancouver). Tens of thousands more live along fiord edges and the valleys leading north through the mountains (for example, the town of Squamish). The urban built-environments are modern and affluent, developed primarily over the last 100 years as a Pacific port facility, transporting natural resource riches and importing manufactured goods, and being the financial hub of British Columbia. Typical of delta and port cities, it has many bridges and extensive exposure to water from the river and the ocean. Industrial and port facilities and railways were built on land created by filling shallow coastal waters. Metro Vancouver's primary hazard threats are flooding and earthquakes. Communities like Squamish to the north face these same hazards, landslides, debris flows, and rare volcanic eruptions.

Present risk mitigation strategies for earthquakes, floods, landslides, and fires are primarily structural. They include incorporation of building codes, dykes, berms, building on elevated pads in floodplains, debris flow catchment basins, rock stabilization, and fire-retardant house materials near forests. A few examples of mitigation through land use include development restrictions in recurrent landslide areas.

The Risk-Based Land Use Guide

In a pilot program begun in 2010, stakeholders are creating a risk-based land use guide for the Metro Vancouver region. Presently, stakeholders in this process include land use planners, city managers, permit and licensing staff, engineers, critical-infrastructure owners and managers, insurers, researchers and practitioners of land use policy, and emergency managers and disaster reduction policy advocates from all levels of government. The land use guide builds on Murray Journeay and colleagues' risk assessment guide created from strategic planning with the town of Squamish.

The land use guide principles include those that are stakeholder built and managed, using existing local instruments that incorporate informed practice; a balance of social, economic, and environmental concerns; transparency of knowledge; and community engagement. Local guide-creation workshops build capability in risk-based land use evaluation. Stakeholders create the guide together to ensure it is practical, applicable, and usable, and incorporates local knowledge. By connection with researchers and a practitioner network, global informed practices are identified and incorporated. Key factors of the guide include risk management instruments needed to be in place prior to a proposal evaluation (for example, hazard zonation). It provides a methodology to identify the hazards, assess the hazard potential, decide which hazards pose a threat, create an inventory of assets under threat from the hazard, determine potential losses from hazard events, identify mitigation options to reduce potential losses to community-acceptable levels, implement the mitigation, and monitor the mitigation implementation.

British Columbia requires all developments be made "safe" for intended use, though it does not describe how to calculate safety or make a development safe. Each municipality is expected to make those determinations. The risk-based land use guide will describe how to calculate the factor of safety and provide options to reduce the risk to tolerable levels. For example, the guide will describe how to set up hazard zones with special land development requirements prescribed to mitigate those hazards, how to integrate risk mitigation into official strategic plans, how to take advantage of land use types that minimize exposure to a hazard, and how to determine a proposal's hazard risk.

Risk Assessment Guide

Any evaluation of the safety of a land use proposal or strategic growth plan requires a method to determine the risk of development and use. Murray Journeay piloted a project to develop and test methods of land use risk assessment with the municipality of Squamish, which included testing the disaster loss estimation tool Hazus-MH. The initial study created and demonstrated the application of risk assessment for earthquakes, floods, and landslides in development of a low-risk community-driven strategic growth plan. The Squamish study demonstrated the value of and a methodology for community engagement in hazard and threat identification and evaluation priority setting, for application of quantitative risk assessment, and for comparing risk between existing and various potential future built environments. Comparing the risk of various future built environments determined a potential quantifiable risk reduction for certain growth plans, thereby measuring the benefit of land use risk mitigation options. It demonstrated the potential savings in dollars and lives.

Journeay and colleagues provided a guide for using quantitative risk assessment for strategic planning. Similar methods, though with different scale and emphasis, are applicable to evaluating the safety of development permit proposals. The risk-based land use guide incorporates these methods and others in the context of municipal processes for development applications and strategic planning.

and Stephen Dovers in Australia suggest that several public policy issues have impeded implementation of hazard risk mitigation: (1) government institutions dealing with disasters were designed for response rather than prevention, (2) the perception of disaster assistance as a social entitlement, (3) concern about imposing limitations on the use of private property, (4) the organizational fragmentation of mitigation effects, (5) the costs of mitigation programs (such as public acquisition of hazard-prone lands), and (6) understanding the extent of savings provided by hazard risk mitigation. As the 2011 earthquake and tsunami events in Japan have shown, even disasters with "natural" triggers can generate very long-lasting impacts globally. Short-term goals of response—saving lives and protecting assets—have to be negotiated with more strategic, longer planning horizons located within broader policy and institutional settings that recognize the impact of individual and local decisions on the economic, social, and environmental viability of a nation. This is particularly important under the conditions of changing climate and increasing uncertainty. Practical and scientific evidence has demonstrated the economic, social, and environmental return on mitigation investment. For example, Public Safety Canada reported benefit-cost ratios for flood prevention measures in Australia, the United States, and the United Kingdom as 3:1, 4:1, and 5:1, respectively. According to Charlotte Benson, John Twigg, and the ProVention Consortium, a Vietnam Red Cross mangrove planting program implemented in eight provinces to provide protection to coastal inhabitants from typhoons and storms cost an average $0.13 million a year over the period 1994 to 2001 but reduced the annual cost of dyke maintenance by $7.1 million. The program also helped save lives, protect and generate new livelihoods, and explicitly incorporate local indigenous knowledge in hazard mitigation.

Indigenous Knowledge and Mitigation

Indigenous knowledge increasingly informs mitigation decisions to better reduce the impacts of disasters. The compatibility of indigenous knowledge with scientific knowledge is a central component in developing meaningful mitigation strategies at a local level. For successful outcomes, it is necessary to facilitate culturally sensitive communication strategies between local people and the scientific community. This knowledge sharing must be based on the assumption that transparent knowledge exchange can aid local communities in addressing their own mitigation strategies while enhancing the development of emerging scientific research practices. The 1999 World Conference on Science called for “cooperation between holders of indigenous knowledge and scientists to explore the relationship between different knowledge systems and to foster inter-linkages for mutual benefit.”

Characteristics and Challenges

Although technological advancement has always been a functional component of mitigation, the mid-1980s saw the inclusion of indigenous knowledge as an integral part of the development framework. Indigenous knowledge became increasingly used in designing development projects, with a specific focus on community interventions.

Drawing on popular definitions by J. Flavier and L. Grenier, as well as countless international examples, indigenous knowledge is characterized by the following attributes:

- Locally bound, indigenous to a specific area and community
- Culture and context specific
- Nonformal
- Orally transmitted and generally not documented
- Dynamic and based on innovation, adaptation, and experimentation
- Closely related to survival and subsistence for many people worldwide

Although the value of incorporating indigenous knowledge and mitigation practices has been acknowledged, this integration has not been seamless and has met several challenges. One challenge is that indigenous knowledge can be classified based on geographical, thematic, and organizational contexts, and in many cases, these overlap. Another challenge is that indigenous knowledge is orally transmitted, and thus implementation is not traditionally documented. This challenge is twofold; first, outsiders to this knowledge may not fully understand its true depth, and second, when this knowledge is documented, it may be impossible to capture culturally specific nuances within the confines of written text.

From Theory to Practice

It is necessary to understand the foundational principles of indigenous knowledge, analyze them in tandem with scientific observations and logic, and apply these lessons into practice. The following explores an example of indigenous knowledge through the facet of local technology systems.

Amir Ali Khan provides an example of earthquake-safe traditional housing practices through an exploration of case studies in Japan, Turkey, El Salvador, Peru, Kyrgyzstan, Italy, Nepal, and India. Because of the relatively high frequency of earthquake events, traditional peoples living in these areas devised safer construction techniques to protect their homes against earthquake shaking. These techniques have evolved over time to reflect the environmental, cultural, and historical context in which they exist and reflect cross-generational experience of earthquake-safe construction practices. Building techniques were based on locally available resources to address local needs. In these countries, houses built using earthquake-safe traditional construction practices have been able to successfully withstand significant earthquake forces.

Khan demonstrated the need to integrate indigenous knowledge with the technical and scientific practices of mitigation. This can be done in two ways: first, by encouraging the inclusion of indigenous knowledge in the decision-making process; and second, through education and awareness raising of communities and stakeholders, including agencies of government, nongovernment, academic institutions, and communities. This integration and inclusion is best done in the local community, with its shared culture and geography.

Land Use Planning for Reducing Losses

Natural hazard researchers have identified local government land use planning as a critical activity for reducing natural hazard–related losses and creating disaster-resilient communities. In theory, local governments can use land use planning to reduce losses by controlling both the location and the design of new development projects that are reviewed under their jurisdiction. To be most effective in reducing losses, local governments can use land use planning to steer new development away from hazardous areas completely. When communities decide to allow development in hazardous areas, local governments can use land use planning to reduce potential losses by directing development to the least hazardous portions of project sites and/or by requiring the use of construction practices that help reduce hazard risk.

Hazard Assessments

Recent scholarship has sought to locate the concept of land use planning for natural hazard mitigation within the broader framework of sustainability and sustainable development, with poor land use planning that fosters hazard vulnerability being viewed as inherently unsustainable. Sustainable land use planning in this context requires at a minimum that decision makers be adequately informed regarding local hazard risks. To make informed decisions, government land use officials must have accurate data regarding the vulnerability of people, buildings, and infrastructure in their jurisdiction, as well as the probabilities of different hazardous events occurring across different geographic locations. Local officials must also understand how different land use decisions can affect these vulnerabilities and probabilities.

Such information can be gathered through the process of hazard assessment, which provides the factual basis for decision makers to estimate the likely costs and benefits of alternative land use scenarios and various strategies for reducing risk. Hazard assessment should proceed according to a three-step process as follows:

- *Hazard identification:* Defining the magnitudes and probabilities of natural hazards that might pose threats in a given area
- *Vulnerability assessment:* Characterizing the populations and property exposed to hazards and the extent of injury and damage that might result from natural hazard events in a given area
- *Risk analysis:* Combining hazard identification and vulnerability assessment data to provide a complete description of risk from the full range of possible natural hazard events in a given area

When applied to future land use, hazard assessment can be used to identify hazardous areas where new development should be discouraged and/or prohibited. Hazard assessment can also be used to reduce risk in areas that have already been developed by providing the justification for required retrofitting aimed at reducing risk.

Land Development and Construction

Land use planning researchers have recently turned their focus to the potential for alternative land development and construction practices to reduce hazard risks. One series of published papers from a national study of alternative subdivision design examined New Urbanist subdivisions (i.e., subdivisions that are characterized by relatively high housing densities, mixed land uses, and pedestrian-friendly design features) and their potential (relative to conventional subdivisions) to reduce losses from flood events. In particular, the authors of the papers argued that New Urbanist design features should theoretically serve to foster additional protection of sensitive floodplain areas and the incorporation of stormwater best management practices.

Other recent studies have examined the relationship between construction practices and subsequent flood losses. These studies found that construction practices that involve altering and/or destroying natural wetlands during the construction process are likely to result in increased flood losses that stem in part from the decreased capacity of the natural landscape to manage floodwaters. The studies also found that construction practices that result in increased quantities and distribution of impervious surfaces also lead to increased flood losses. In response, the authors recommend that land use planning be utilized in order to protect existing wetland areas and to limit the installation of impervious surfaces into the natural landscape.

Hazard Vulnerability Analysis

The overarching goal following a crisis is to minimize its impact on an organization and return the organization to its pre-event status as quickly as possible. The hazard vulnerability analysis (HVA) is a systematic approach to thoroughly examining a hazard, the probability of a hazard becoming an event, and the resultant risks to the organization in question. A completed HVA serves as a tool used to prioritize hazards, thus giving emergency planners a way to focus resources. This article further defines a hazard vulnerability analysis, explains each component of an HVA, discusses limitations to HVA, and suggests how to conduct an HVA.

In the discussion of crises, the terms *risk*, *threat*, and *hazard* are often treated as interchangeable. For the purposes of this article, the following definitions will used. A hazard can be defined as anything that may pose a danger to an organization or institution. An event occurs when a hazard is realized and it has had an impact on an organization or institution. Risk is a measure of the probability of damage to life, property, or the environment upon the manifestation of a hazard.

Once a hazard is identified, the probability of its becoming an event is quantified according to the following formula:

$$\text{(Probability)} \times \text{(Risk)} \times \text{(Preparedness)} = \text{Vulnerability}$$

Several methods have been developed to quantify these terms. A properly performed HVA should differentiate hazards so that planners are provided with a focal point for preparedness and mitigation. Having the support of organizational leadership prior to performing an HVA is critical to its success. Without this support, findings and subsequent recommendations may never be realized. Leadership may not adopt all the recommendations, but efforts must be supported and championed from above.

Hazard Identification

Traditionally, organizations focus on natural disasters, including hurricanes, earthquakes, and floods; however, in today's environment, this may be rather shortsighted. A broad review of all hazards must be examined, especially given the global interconnectedness of our world. Table 1 refers to a partial list of hazards that should be considered.

Table 1 Hazards that should be considered

Natural events	Technological events	Human events
Hurricane	Electrical failure	Terrorism
Tornado	Generator failure	Failure of government
Severe thunderstorm	Fuel shortage	Law enforcement events
Blizzard	Sewer failure	Labor actions
Ice storm	HVAC failure	Supply chain issues
Tsunami	Fire	Bomb threat
Temperature extremes	Hazmat (internal/external)	
Drought	Structural damage	
External flood	Loss of IT systems	
Landslide	Loss of key department	
Volcano		
Epidemic		

Since this is not an exhaustive list, any hazard to an organization must be considered. A truly comprehensive review also considers hazards to business operations. It is important to look not only locally but globally as well; for example, obtaining raw materials from a foreign country that undergoes a nationwide labor action or political upheaval can result in supply chain issues.

Considerations for Hazard Identification

Dividing personnel into small workgroups is an effective way to evaluate a specific set of hazards. Each group should be composed of subject-matter experts in the areas to which they are assigned. For example, plant engineering should be represented in workgroups that examine hazards impacting infrastructure. Any group evaluating information technology (IT) hazards must have an IT professional as a member. Using this broad-based approach ensures a more thorough understanding of the capabilities and limitations of each department. If any international hazards are identified, it is best to consult members of the organization who have cognizance in international operations. The development of a large list that identifies all hazards, no matter how improbable they may seem, is preferable to having a list that fails to identify a potential hazard. The next step, after hazards have been identified, is to determine the likelihood that they may occur.

Probability

Probability—the likelihood or chance of something—can help determine vulnerability. Previous occurrence of a natural event can assist in determining the probability of its reoccurrence. History of occurrence based on geographic location can be found at a number of open-access Web sites, including those the National Oceanographic and Atmospheric Association (NOAA), National Weather Service (NWS), and National Geological Survey, all of which are well-recognized sources of information. State, local, and regional agencies, particularly local emergency planning committees (LEPCs), may also provide information. Federal law requires that producers and users of hazardous materials above certain quantities inform local agencies as well as provide contingency plans to local emergency planning committees. Establishing relationships with local organizations may provide insight into what the local community perceives as vulnerability and may lead to better cooperation and coordination during an event.

Quantifying the probability of an event can be difficult. The American Society of Healthcare Engineers (ASHCE) and Kaiser Permanente have implemented a simple 0–3 scale, with 0 meaning no probability and 3 meaning high probability. Further stratification occurs by applying a similar scale to risk and preparedness.

Risk

Risk is defined as the negative outcome when a hazard is realized and an organization or institution is negatively affected. Although many more exist, six areas of risk should be considered: threat to life and health, disruption of services, possibility of damage and failure, loss of community trust, financial impact, and legal issues.

The type, magnitude, location, and duration of impact on the environment must be considered when evaluating risk. Intangible impacts, such as loss of goodwill and reputation, must also be considered. Negative press regarding environmental contamination or violation of regulations may have a long-lasting impact.

Life, safety, and health should take priority when evaluating any hazard. The organization's role in the community (public versus private, service versus manufacturing, etc.) will determine which of these areas have the greatest risk to the organization. A 1–5 scale can be used to help further stratify the risk; the higher the number, the greater the risk.

Preparedness

Preparedness is an organization's state of readiness to respond to an event. The five major variables to examine when determining an organization's preparedness include status of current plans, training status, insurance, availability of backup systems, and community resources. Are the organization's responsible recovery plans up to date? Are the initial planning assumptions used to develop plans still valid? Difficult economic times have forced organizations to do more with less, often leaving a single person in charge of multiple areas. Should an event occur, can one person be effective in disaster response, given competing responsibilities? Can the organization continue normal operations when there is an interruption of supplies? Just-in-time logistics have replaced the warehousing of key supplies and materials, and the assumption that the organization can continue normal operations, even for several days, may no longer be valid.

An annual review of contingency plans should be the minimum requirement. Turnover of personnel and changes in responsibility must be accurately tracked. If this information is not reviewed on a regular basis, the information cannot be counted on as accurate, greatly hampering both response and recovery efforts. This is especially true in the first few hours of an event, when key people are needed most.

Training of individuals is a key component of any preparedness program. Key leaders should be trained in the principles of incident command and incident management. Many skills

Table 2 Natural events (probability) × (risk) × (preparedness) = vulnerability

	PROBABILITY				RISK					PREPAREDNESS			
	HIGH	MEDIUM	LOW	NONE	LIFE THREAT	HEALTH/ SAFETY	HIGH DISRUPTION	MODERATE DISRUPTION	LOW DISRUPTION	POOR	FAIR	GOOD	
EVENT	3	2	1	0	5	4	3	2	1	3	2	1	SCORE
Hurricane		X					X				X		12
Tornado			X				X				X		6
Severe thunderstorm		X						X			X		8
Snowfall	X							X				X	6
Blizzard	X							X				X	6
Ice storm	X							X				X	6
Earthquake			X		X						X		10
Tidal wave				X	X						X		0
Temperature extremes		X							X			X	2
Drought		X							X			X	2
Flood, external			X						X		X		2
Wildfire			X						X			X	1
Landslide			X						X	X			3
Volcano				X						X			0
Epidemic	X						X				X		18

used during day-to-day operations can be utilized but are rarely sufficient. The time frame in which decisions must be made and the amount of available information prior to making a decision vary greatly in crises when compared to regular operations. The amount of time in which to make a decision is greatly compressed. Often, some amount of information desired prior to making a decision is unavailable. The time required to gather information is often unavailable, forcing people out of their comfort zone to make decisions with a paucity of information. Making the wrong decision is often preferable to not making any decision.

Training in the terminology and principles of an incident command system is necessary in order to adequately integrate into the community's response plan, even though not every organization may adopt a formal incident command system itself. Leadership and crisis-response staff should have a working knowledge of these principles. There are several no-cost and low-cost training programs available from the Federal Emergency Management Agency (FEMA).

Frequent training exercises and drills aid in identifying inadequate response plans and give leaders an opportunity to exercise leadership in a safe but stressful environment. Realistic scenarios based upon the vulnerabilities identified in the HVA are best. Effective programs provide time and personnel dedicated to developing, administering, and evaluating drills and exercises. An effective program should not have key responders both develop the exercise and participate in the drill. Responders' participation in the running of a drill makes an impartial assessment difficult. Employing an impartial organization, either internally or by subcontracting specialists, allows an unbiased look at an organization's program.

Adequate insurance coverage should be part of any preparedness program. The insurance portfolio should include policies to cover physical loss of buildings, infrastructure, and supplies as well as loss of revenue. Insurance companies may require specific plans or specialized procedures to be in place to protect the organization from loss. Having a thorough and accurate inventory of all equipment, supplies, and infrastructure will greatly speed the filing of any claim and assist in reimbursement from local, state, and federal agencies. Having adequate response plans and procedures in place may also reduce exposure for the insurance company, potentially leading to decreased insurance premiums.

Status of backup systems should be thoroughly evaluated. Examination of processes and procedures may help identify key vulnerabilities to backup systems. These systems may be as simple as a redundant communication system that notifies leadership and management should a primary system become inoperable, or as complex as an off-site data center that maintains full data services should the primary system fail. Developing cross-trained teams from other offices within the organization should be considered prior to requesting community assistance. Most vulnerable supplies should be cached by either putting them into storage or increasing par levels so if an interruption occurs, impact may not be as severe.

As an organization becomes more dependent on technology, uninterrupted supplies of electricity are of ever-greater importance. Facility-wide backup generators may be out of reach for many institutions; however, particularly vulnerable systems can be protected by smaller generators or commercially available uninterrupted power supplies. Having agreements with companies that provide portable generators is a viable alternative. Pre-wiring of the identified circuits to receive power from a commercial generator will save time if an outage occurs.

Finally, the ability of a community to respond should be thoroughly examined. The nature of the event will determine whether one can count on community resources. If the event is localized to a single facility, such as in a fire, resources are often readily available. However, if the disaster is widespread, available resources decrease dramatically.

Relying on support from governmental agencies as the cornerstone of any preparedness program is fraught with difficulties. Each organization should prepare itself for independent operations for a minimum of 96 hours. When considering entering into agreements with organizations to provide key services, during or after an event, consider other commitments by those vendors to provide the same services. It is not uncommon in today's consolidated business environment to have committed resources to multiple organizations. If the event is widespread, vendors may not be able to meet their obligations and alternatives must be considered. A scale of 1–3 can be used, with 1 representing well prepared, 2 being fairly prepared, and 1 being poorly prepared.

Putting It All Together

Below is an example of an HVA using the ACHE format for natural events. In this formula, the probability of 0 (no risk) to 3 (high risk) is used. Risk is classified from 1 to 5, with 5 identifying the greatest threat and 1 identifying low disruption. An inverse scale is used to identify preparedness, with 3 representing poorly prepared and 1 representing well prepared. The scores from each are multiplied using the following formula:

$$\begin{gathered}(\text{Probability}) \times (\text{Risk}) \times (\text{Preparedness}) \\ = \text{Vulnerability}\end{gathered}$$

The product of all three factors gives a quantitative value to the vulnerability. If there is no probability of a hazard, a score of 0 is assigned; basic arithmetic functions then yield a vulnerability of 0. In this example, a higher number given to preparedness identifies an organization less prepared.

Each hazard should be ranked numerically, which will quickly identify any outliers. Efforts need to be focused on the greatest vulnerabilities. The completed HVA should be shared with members of the organization and should be used to gain consensus on where and how resources should be utilized. Completing an HVA annually will help determine if preparedness efforts have reduced existing vulnerabilities or if any new vulnerabilities have been identified.

An HVA is a valuable tool. If performed properly, it will identify key vulnerabilities of an organization that can then be ranked and prioritized so that resources to mitigate these vulnerabilities can be correctly utilized. As mitigations are developed, they should be tested, and training exercises should be performed regularly to ensure that they remain valid.

Hazardous Materials

A hazardous material is any item or agent (biological, chemical, physical) that has the potential to cause harm to humans, animals, or the environment. A hazardous materials spill occurs when hazardous materials are released in an uncontrolled manner. This can happen while a substance is being transported or at a fixed facility. One example is the oil spill resulting from the April 20, 2010, explosion of the Deepwater Horizon offshore drilling rig that released more than an estimated 200 million gallons of crude oil into the Gulf of Mexico. According to the U.S. Department of Transportation, there were 14,953 hazardous materials incidents (1,389 air incidents, 12,750 highway incidents, 743 rail incidents, and 71 water incidents) in the United States in 2011 alone.

Those who use hazardous materials are required by law to report the substances being used so emergency responders know which materials may be involved in a hazardous materials incident in their jurisdiction. Vehicles transporting hazardous materials, such as railway cars and tractor-trailers, are required to be placarded with basic information about the materials they are carrying.

Hazardous Materials Identification

There are two main systems by which to identify hazardous materials. One system was developed by the U.S. Department of Transportation (DOT), and a related system was adopted by the United Nations (UN). The National Fire Protection Association (NFPA) developed an additional system of placard information.

The DOT/UN system uses a diamond-shaped placard on vehicles transporting hazardous materials. Labels are used on other types of containers. Each hazardous substance is assigned a class for identification purposes. The class of the substance is displayed on the placard in the form of a four-digit number. The placard itself is in the shape of an 11-inch diamond and has to be displayed on all four sides of the vehicle.

Placards and labels are required on all shipments of the most dangerous materials, which include radioactive materials, water-reactive flammable solids, explosives, and some dangerous poisons. Placards are also required on shipments of less dangerous hazardous materials when the shipment contains more than 1,000 pounds of the substance.

The Emergency Response Guidebook (ERG) is developed jointly by Transport Canada, the U.S. Department of Transportation, and the Secretariat of Communications and Transportation of Mexico (SCT). The ERG contains a list of the four-digit codes and the chemicals they represent. The ERG is intended to be used by emergency responders to help them identify any hazardous materials at the scene of an incident. The ERG also provides information on how responders can protect themselves and the public from the hazardous material in question. The manual outlines the particular fire or explosion dangers of the substance where applicable, as well as the health risks if one is exposed to the material. The ERG includes information on the recommended protective clothing emergency responders should wear while working near the substance and suggests evacuation distances to protect people from large spills.

There are nine categories of hazardous materials, and the hazard class of dangerous items is indicated either by its class/division number or by name, as listed below:

- Hazard Class 1: Explosives
    - » Division 1.1 Mass explosion hazard
    - » Division 1.2 Projectile hazard
    - » Division 1.3 Minor blast/projectile/fire
    - » Division 1.4 Minor blast
    - » Division 1.5 Insensitive explosives
    - » Division 1.6 Very insensitive explosives
- Hazard Class 2: Compressed gases
    - » Division 2.1 Flammable gases
    - » Division 2.2 Nonflammable compressed gases
    - » Division 2.3 Poisonous gases
- Hazard Class 3: Flammable liquids
    - » Flammable (flash point below 141 degrees)
    - » Combustible (flash point 141–200 degrees)
- Hazard Class 4: Flammable solids
    - » Division 4.1 Flammable solids
    - » Division 4.2 Spontaneously combustible solids
    - » Division 4.3 Dangerous when wet solids
- Hazard Class 5: Oxidizers and organic peroxides
    - » Division 5.1 Oxidizer
    - » Division 5.2 Organic Peroxide
- Hazard Class 6: Toxic materials
    - » Division 6.1 Material that is poisonous
    - » Division 6.2 Infectious agents
- Hazard Class 7: Radioactive material
    - » Radioactive I
    - » Radioactive II
    - » Radioactive III
- Hazard Class 8: Corrosive material
    - » Destruction of the human skin
    - » Corrode steel at a rate of 0.25 inches per year
- Hazard Class 9: Miscellaneous
    - » Miscellaneous hazardous materials or substances

NFPA System Placards

The NFPA system of hazardous material identification is also widely used. This system uses the same diamond shape as the DOT system and subdivides the diamond into four smaller diamonds, each of which is color coded. Each color has a particular meaning:

- Blue—health risk
- Red—flammable material
- Yellow—reactive
- White—special characteristics or information, such as whether water can be safely used on the substance

Each colored diamond displays a number indicating the degree of risk of that material. These numbers range from 0 (no risk) to 4 (greatest risk). As an example, a highly flammable material could have a 4 in the red diamond.

Routes of Exposure

There are four main routes of exposure by which chemicals can enter a body: inhalation, skin contact, eye contact, and ingestion. Chemicals in the forms of gases, vapors, dust, or mist may be inhaled through the mouth or nose. Many chemicals can cause irritation, itching, or swelling when they come in direct contact with the skin, and some chemicals can be absorbed through the skin. Chemicals can also enter the body through contact with the eyes. Gases, vapors, dust, or mist can all come in contact with the eyes. Additionally, liquids can be splashed into the eyes. Chemicals may be ingested through the mouth by swallowing. This can result from hand-to-mouth contact or consuming contaminated food or beverages.

Personal Protective Equipment

It is essential for emergency services personnel to wear personal protective equipment (PPE) when responding to hazardous materials incidents. There are three zones (cold, warm, and hot) in a hazardous materials incident that correspond to the level of protection one needs in order to safely work within that zone. Each zone is discussed in further detail below.

Personnel who enter the warm or hot zones need to wear appropriate protective clothing and equipment. There are four basic levels of protection, with the highest being Level A and the lowest, such as street clothing, being Level D. A person wearing Level A equipment is theoretically protected for short exposures in an atmosphere that is immediately dangerous to life and health (IDLH), and for prolonged work (such as cleanup operations) in contaminated areas identified as having a short-term exposure limit.

Air purification devices or self-contained breathing apparatus (SCBA) help minimize the risk of inhalation exposure and should be used by personnel in any IDLH atmosphere. An IDLH atmosphere is one in which the maximum to which a healthy worker can be exposed to the substance in question is 30 minutes in order to escape without suffering irreversible health effects. Personnel who remain in the cold zone should still wear PPE, including gloves, face shields or safety goggles, masks, and overboots, to prevent accidental exposure to the hazardous substance.

Four Levels of Personal Protective Equipment

The following list details the four levels of personal protective equipment (PPE)—A, B, C, and D:

- Level A is the highest level of protection. This is a fully encapsulated chemical-resistant suit with a double layer of chemical-resistant gloves, chemical-resistant boots, airtight seals, and SCBA.
- Level B protection includes a chemical-resistant, long-sleeved suit with double layer of chemical-resistant gloves and chemical-resistant boots. Those using Level B protection still need to use SCBA to enter the hazardous environment.
- Level C protection includes an air-purification respirator, chemical-resistant suit, chemical-resistant outer gloves, and chemical-resistant boots.
- Level D is the lowest level of protection and does not provide respiratory protection. Regular work clothes would be considered Level D protection.

Control Zones

As mentioned above, there are three main zones within which one may operate at a hazardous materials incident. The hot zone is an area into which only those with the highest level of protective clothing can enter. The hot zone is sometimes also referred to as the exclusion or restricted area.

The warm zone is the control area immediately outside the hot zone. It is also referred to as the decontamination or limited access area. Only those properly trained and equipped to assist with decontamination should enter this area. The inner and outer borders of the warm zone might be as far as 120 feet apart, depending on the scope of a particular operation.

The cold zone may also be referred to as the clean area. This is where the command post is located. Transport lines form in this zone to receive patients as they are passed outward.

When responding to a hazardous materials event, emergency personnel should approach the scene from uphill and upwind to prevent accidental contamination. This is more feasible when responders know ahead of time about the possibility of entering a hazardous environment. In some instances, personnel may enter the hazardous environment before they realize the nature of the situation.

Decontamination

One of the most important principles of handling hazardous materials is to prevent further contamination. All people and equipment involved in the incident need to be decontaminated in order to remove the substance. All materials used for decontamination, such as the water used for washing and flushing the area, also need to be disposed of properly.

There are four general types of decontamination, as follows:

- Mechanical decontamination involves brushing or wiping substances (such as dust or powders) off the victim. This is the first step of gross decontamination.
- Dilution involves washing the substance off, most often with plain water. If the hazardous material is water-reactive (such as sodium or lithium) or nonsoluble, detergent should be added to the water in order to remove the substance.
- Degradation is the chemical alteration and neutralization of the hazardous nature of a substance. This process may be used on

equipment but is not practical for use on people.
- Isolation of remaining hazardous materials as well as materials used for decontamination is also necessary. Collection systems for water runoff, for example, are important, and in some jurisdictions mandatory. Hazardous materials should not be allowed to run into the drainage system.

There are several resources available for information on what to do when dealing with various types of dangerous substances. Some are more appropriate for individuals, while others are geared toward emergency response personnel. CHEMTREC is a private service for information about chemicals involved in transportation accidents. The Centers for Disease Control and Prevention (CDC) provides information about biologic and disease-related hazards. There are nearly 40 regional poison control centers that cover all regions in the United States. Finally, the National Pesticide Telecommunications Network (NPTN) is a 24-hour service for information related to pesticide exposures and accidents.

Hazardous Waste Disposal

Hazardous wastes are defined by the Environmental Protection Agency (EPA) as substances that have no commercial value and cannot be sold or recycled. These substances primarily include secondary waste from commercial and industrial activities, such as leftover chemicals at dry cleaning facilities or hazardous by-products used in the manufacturing process. These substances often include mercury, agriculture chemicals, benzene, and other hydrocarbons such as used motor oil. Hazardous wastes may also include the leftover by-products used to manufacture illegal drugs such as methamphetamines. Hazardous waste products are highly regulated throughout the industrial world. This is primarily because of the environmental and health hazards that they pose.

Concerns

Various accidents have occurred involving hazardous waste products, resulting in thousands of deaths as well as multiple sites that require cleanup. In many areas of the world, the water supply has become so contaminated with hazardous waste there is little potable water available. In other areas, lakes and rivers that are commonly used by communities and villages to supply both potable and nonpotable water resources are completely unusable. The vast majority of hazardous chemicals are generated from household use, such as pesticides, household cleaning supplies, and related materials. Many households are unfamiliar with how to properly use these chemicals, which results in hazardous waste products. Moreover, these products are often poured down the drain or flushed into the toilet, which may result in the contamination of the local water supply or the ground surrounding the home. Unfortunately, few homeowners realize just how hazardous this waste can be until family members become ill. Luckily, private organizations and government agencies have implemented local recycling efforts so that homeowners have a place to drop off their hazardous waste materials.

Children and adults alike have suffered as a result of poorly managed hazardous waste sites. This has resulted in a large occurrence of non-treatable cancers, respiratory illness, deformities in newborns, and children born with delayed mental faculties. This is especially common in underdeveloped countries where large industrial organizations have relocated because of a lack of environmental enforcement by the government. Bribery of officials has also been documented in these countries, with the result that illegal hazardous waste operations are often overlooked. In some cases, entire provinces or large sections of land are no longer usable. Humans are no longer able to occupy these areas.

These illegal sites not only affect humans, they also affect wildlife. Many countries have seen entire species eliminated as a direct result of illegal hazardous waste sites. However, the majority of hazardous waste sites completely follow all legal and regulatory standards while managing this waste. Local emergency planning committees (LEPCs) have been formed in most communities to keep the public informed and assist these hazardous waste sites in their efforts to follow the law. Large industrial producers of hazardous waste are required to complete Tier II reports each month and send these reports to local and state officials. State emergency response commissions (SERCs) have been formed in order to manage hazardous waste sites and to manage incidents involving accidental releases of hazardous waste materials.

Steven Guy shovels up what remains of his house after an EF-4 tornado hit on April 27, 2011. Hazardous waste from disasters must be separated from other debris such as wood, electronics, large appliances, and household garbage for proper disposal.

Background

The U.S. Congress passed the Resource Conservation and Recovery Act (RCRA) in the mid-1980s in an effort to regulate the generation, storage, treatment, transportation, and disposal of wastes considered to be hazardous. Congress gave oversight of this act to the EPA, which also allows some states to regulate their own hazardous waste under the law. The law was passed in response to an increase in the number of hazardous materials being released into the air as well as into the groundwater by individuals, service industries (e.g., dry cleaners), and manufacturers. Scientific evidence suggests an increase in the number and types of cancer and other medical conditions in the areas near these releases. Moreover, several historical incidents involving hazardous wastes have occurred, prompting the public to demand that the federal government pass laws concerning hazardous wastes. These incidents include the Hercules Chemical Plant in Jacksonville, Arkansas, which manufactured Agent Orange for the military during the Vietnam War, and several waste pit owners, who were accused of dumping hazardous waste into local rivers.

In addition to the United States, many other industrialized countries also have regulations concerning hazardous waste. These regulations include the Framework Directive on Waste (European Union), the National Solid Waste Policy Bill (Brazil), and the Regulation of Exports and Imports Act (Australia). Other countries, such as South Africa, Mexico, and India, have similar regulations in place. Moreover, international treaties such as the Basel Convention (1992) and the Waigani Convention (2001) formalized agreements between 151 countries that serve to minimize generation, prevent unlawful disposable, control and reduce international movement, and ensure sound management practices associated with disposal of hazardous wastes. These conventions also establish mechanisms to prosecute those accused of unlawfully disposing of waste.

Regulatory Efforts

Aside from regulations and laws such as RCRA, the U.S. Congress passed the Superfund Amendments and Reauthorization Act (SARA) to assist with the cleanup of illegal hazardous waste sites. Moreover, the act provides a funding mechanism for hazardous wastes sites that are so large the owner is unable to pay for their cleanup. Some of these sites may have been legitimate sites that experienced an extraordinary event, such as an accidental spill, or they may have been sites that operated outside their state or federal authorization. However, the United States has so many sites there is not enough funding available to pay for the cleanup. Therefore, the EPA has created a list of sites based upon priority. The sites that have the potential of affecting the largest number of citizens are usually placed at the top. These sites may have contaminated the local water supply, may be located near a school, or have the potential to affect entire communities.

Citizen groups such as the Sierra Club have not only researched the effect of hazardous wastes on the population and the environment but have also enlisted respected scientists to help them promote change. These groups have helped open forums with citizens and government leaders, presented scientific research in well-respected journals, and filed lawsuits against private companies and the government. Many of these efforts have led to enforcement activities, including successful prosecution of illegal waste operators and cleanup of illegal sites. Medical leaders have also joined these efforts by researching high rates of cancer in these areas.

A global reduction in the economy that started in 2008 significantly reduced the management of hazardous waste concerns. Although the regulations and laws on the books never changed and the EPA and similar agencies still require the transport and disposal of hazardous waste per law, reductions in investigative staff may have contributed to an increase in illegal waste sites. Moreover, many companies filed for bankruptcy and simply closed, leaving hazardous materials behind. Local, state, and federal agencies were left with the responsibility of locating the owners and trying to prosecute them. These agencies were also left with the responsibility of securing the sites and trying to find funds to remediate them. Because bankruptcy courts are charged with ensuring that any remaining assets are paid to creditors, government agencies often have found that their hands are tied when trying to penalize these companies. This has not stopped them from prosecuting the company leaders.

Additional current efforts include changing how hazardous waste is classified so that the public has a better understanding of these hazards. These efforts include changing warning placards on transportation vehicles such as trucks and ships and informing the public where hazardous sites are located. However, with the advent of the global war on terrorism and concerns about domestic terrorism, the U.S. Department of Homeland Security is attempting to change how these notifications are made. Additionally, these efforts include removing placards and signage so that potential terrorists are unable to access hazardous waste that may be used in creating a weapon of mass destruction (WMD).

Health and Medical Response Scenarios

Health and medical care staff and systems play key roles in the response and recovery from crisis events (such as mass transportation accidents and acts of terrorism). Disasters such as Hurricane Katrina and the 2011 Japanese tsunami illustrated how hospitals could be destroyed or rendered unusable. Under such circumstances, hospitals and medical staff have to establish and work from ad hoc facilities. Even if remaining intact, hospitals will have to operate at considerably reduced capacity as a result of, for example, losses in infrastructure (such as damage to buildings and equipment and loss of critical care facilities) or in staff (pandemic influenza creates patient surges at the same time as staff availability is reduced by increasing infection rates). Crises result in staff having to work long hours, often in temporary locations, while possibly having to contend with personal loss and increased threats to themselves and their families (such as the risk of infection from pandemic or biohazard events).

Being able to respond to crises requires the development of crisis management systems, competencies, processes, and procedures. This commences with planning for worst-case scenarios that identify the circumstances and consequences hospitals and their staff could encounter. This article outlines the context in which medical response planning occurs and discusses what hospitals and medical staff can do to adapt to crisis circumstances and consequences.

Context

Health and medical crisis management starts with anticipating the point where the surge in demand from a crisis event will overwhelm normal capabilities and resources. This could occur acutely (for example, with an earthquake) or over time (as with a pandemic). Identifying where this occurs signals where crisis management activities and processes are required to accommodate issues such as the following:

- Hospitals overwhelmed to the point of actual functional collapse
- Staff working in ad hoc, remote treatment centers
- Staff working with representatives of several departments, agencies, and jurisdictions
- Infrastructure/service failure or intermittent access to services and utilities
- Reconciling inpatient and survivor medical needs
- High levels of public risk and multiple deaths
- Distressed publics seeking guidance, information, and services
- Dealing with the worried well
- Staff shortages from lack of availability, exhaustion, or sickness that increase over time
- Staff concerns for workplace and family safety
- Public searching for friends and relatives in hospitals
- Blood shortages
- Integrity of information channels being overwhelmed, disrupted, or lost
- Medical supply and personal protection equipment inadequacies, shortages, and losses
- General practitioners seeking advice
- Private hospitals and rest homes seeking advice and/or being overwhelmed
- Mass evacuations into or away from a city
- Large numbers of patients and staff requiring decontamination
- Resource limitations that increase over time

Anticipating these issues provides the foundation for planning that identifies the systems and procedures required to facilitate a capacity to adapt to crises. This work is performed by senior management teams. During a crisis, the senior management group is involved in planning for hospital and staff recovery.

Planning

Crisis management planners develop crisis management policy and the training and organizational development required to ensure that plans can be implemented promptly should a crisis occur. During a crisis, senior management teams identify and procure future resource needs (over

Case Study: Medical Crisis Management Capability Exercise

Outbreaks such as severe acute respiratory syndrome (SARS) and swine flu highlighted the need for medical and health facilities to develop crisis management capability. The rarity of such events and the suddenness with which they can occur makes the use of simulations that provide comprehensive tests of national systems an important tool in developing crisis management capability. This case study discusses an exercise designed to practice and assess key elements of an effective medical crisis management capability including public health interventions (surveillance capability and capacity, early detection and isolation of cases, quarantine of contacts, and use of antivirals); cluster control (contact tracing procedures by public health services, isolation procedures and protocols, reconfiguration of health services, and preparation for establishment of community-based assessment centers); communications with public and media (content and distribution of fact sheets, management of Web site information for consistency and currency, and regular media briefings); and exercise operations centers (capability and capacity of these facilities to effectively operate during a pandemic event).

The exercise included 21 health boards, public health services, the Institute of Environmental Science and Research, and the Ministry of Health. The exercise was evaluated and analyzed using data and information obtained through debriefings with exercise participants, facilitators, and evaluators. Observation notes and comments from evaluators using predeveloped templates, narrative feedback, and feedback were received from 20 district health boards and seven public health service units.

Identification of Needs

Evaluation identified a need for crisis management to address issues relating to policy, procedures, and guidance; systems, tools and processes; human resources; capability and capacity; communications; and monitoring.

A need was also identified for comprehensive policies, procedures, and protocols designed specifically to enable effective and timely response to crisis events. This included developing clear guidelines to inform the establishment and operation of community health resources. To implement the latter, evaluation identified a need for improved crisis management systems and processes. A need to develop communication systems across the health sector to facilitate more effective communications during a crisis was evident. In particular, more attention to clarifying what was required by each agency and function was called for to ensure effective implementation and coordination of response processes. The absence of such coordinating mechanisms resulted in some agencies preferring to follow their own established processes, resulting in a breakdown of a national response that relies on the coordinated use of limited resources. This identified a need to develop clear and consistent communication systems and processes, developing them in a consultative manner to increase sector willingness to engage with developed processes. Consequently, a need for the collaborative development of current systems and tools in ways that contribute to ensuring they are effective and utilized consistently in a crisis was recognized.

The exercise also identified a need for more training in and improved tools for evaluation activities to contribute to the progressive development of crisis management systems and capability. Other findings related to resource availability. Some emergency operations centers across the sector identified a need for more facilities and equipment to enable them to respond effectively during a pandemic crisis. Human resource issues, particularly regarding training and staff deployment resources, were identified, as was recognition that there were insufficient people to perform as efficiently as required. In some areas, further training in coordinated incident management was required to allow staff to better understand their role and increase their capability, particularly with regard to teamwork. Analysis of team functioning highlighted a need for clearer definition of roles and responsibilities across the sector to avoid confusion and misunderstandings and to optimize use of limited resources. A need was found for more trained staff to be available to cover contingencies and additional functions (for example, redeploying child health nurses to surveillance) where required.

During the early part of the exercise, confusion and misunderstanding affected the quality of communication and effective coordination of resources. This was particularly so when new and crucial information was introduced. This identified a need not only for better pre-event communication training but also for the development of better coordination of health sector resources and more effective monitoring of activities being undertaken across the sector during response.

the next week to months) and start planning for hospital and staff recovery and the return to normal functioning. Planning culminates in developing crisis management capability across all hospital functions in ways that accommodate novel demands such as multiagency response, staff roles and deployment, remote treatment needs, and staff ability and willingness to report to work.

Multiagency Response

Planning should extend beyond a given hospital to encompass the regional and multiagency issues required to develop a tiered, scalable, and flexible surge capacity to provide care for prolonged mass casualty events. Planning should involve key stakeholders (emergency medical services; emergency management; public health; public safety/law enforcement; health care systems; hospitals and hospital associations; Red Cross; mental health; jurisdictional legal authorities; professional associations such as pharmacy, medical, nursing, and mental health; and health professional training institutions). This ensures that, as far as possible, all professional, jurisdictional, and regional stakeholder groups likely to have roles and responsibilities are identified and included in the planning process. This can be facilitated using planning models such as the medical and health incident management system. It is also important to consider likely public behavior (such as public reluctance to present to inoculation centers in a bioterrorist event). A failure to anticipate likely public behavior could result in resources being wasted by planners' inappropriate assumptions about public response to medical crises. Planning needs to pay particular attention to issues associated with staff deployment and availability.

Staff Roles, Deployment, and Availability

Planning must consider how preexisting staff roles, functions, and deployments may change during crisis response. For example, staff without ongoing duties could be redeployed (for example, removing debris from hospitals or preparing facilities for patients). To expedite this, it is necessary to conduct staff audits and anticipate staff deployment in relation to crisis demands and needs and not in terms of normal staff roles and patterns of deployment.

Planning should accommodate, for example, identifying the roles and type of staff required, possible threats to staff and their families, the provision of crisis management education and preparedness, and response and support training to develop staff confidence in their role and to mitigate risk in the workplace (risk management protocols, personal protective equipment, and antivirals). All staff should be involved in planning. This ensures that resource use is optimized, staff needs are acknowledged, and training needs are realistic, and that planning increases commitment to training and plan implementation. The importance of the latter derives from the possible need for staff to operate outside normal hospital environments.

Events such as earthquakes can damage infrastructure over a wide geographical area. To accommodate the fact that many survivors will not have immediate access to hospital care, remote facilities to compensate for overwhelmed, damaged, or destroyed hospitals must be established and resourced. Remote settings capable of acting as temporary hospital facilities (such as churches, community centers, government buildings, hotels, medical clinics and surgeries, sports facilities, and warehouses) should be identified. Planning for the operation of remote centers should be modular, in 50-patient increments, to facilitate estimating staffing, resourcing, and administrative needs during response. Plans should also address transportation to and from sites, how health care workers from other agencies or specialist teams will be deployed and integrated into these locations, and how communications will be established to coordinate implementation and communicate with, and provide support for, the public. Good communication with the public may prevent systems being deluged by patients who may not be ill but who have concerns and who are seeking further information or evaluation. The importance of doing so is influenced by the effect a crisis can have on staff availability.

During a medical crisis, some staff may be unable (because of transportation problems) or unwilling to work (because of concerns about their own safety and health, or that of their families). Anticipating staffing issues ensures that plans are based on realistic expectations of what could reasonably be accomplished under different staffing scenarios.

Staffing issues stem from both hazard and risk perception issues. Medical staff are more likely to report for work following weather and geological hazards, as they tend to be more familiar with them. They are less likely to turn up for influenza pandemic events, and even less likely for bioterrorism scenarios. The latter problems reflect medical staff knowledge about the infectiousness of diseases and the implications pandemic and biohazard events have for their health and that of their family. Other reasons why staffing issues can arise in crisis response include:

- Childcare and elder care responsibilities;
- Personal health concerns;
- Confidence in personal safety while at work and/or their ability to perform duties;
- Transportation issues and being able to safely get to work, especially if in a different location;
- Perceived problems accessing vaccines, antivirals, and protective equipment;
- Lack of confidence in the health service/hospital preparedness; and
- Distrust of employers and the credibility of risk information and risk management practices.

Knowledge of such factors informs planning, training, and resourcing (provision of vaccinations and/or antivirals and protective equipment) for health workers and their immediate family. Transportation issues can be addressed by identifying employees with four-wheel-drive vehicles and arranging pickup points for essential personnel. Hospitals can preplan emergency childcare and elder care facilities, and personal health issues can be mitigated by encouraging staff to maintain an emergency supply of medication at work. Staff should be encouraged to develop household and workplace emergency plans (emergency contacts, arranging caregivers, family emergency planning) prior to crisis events occurring. Staff ability or willingness to work illustrates how crises can affect resource availability over time and introduces the need to manage the deployment of limited health care resources.

Crisis Response

In circumstances in which the demands made on medical systems exceed available resources, a key crisis management function involves adapting plans and actions by balancing health care objectives and operational realities (such as standards of patient care against the number of staff available to provide that care). At this level of crisis management, multidisciplinary and multiagency teams are required to balance medical, public health, transportation, and public order issues (such as coordinating with police and transport groups to get patients to remote treatment centers or to hospitals), to prioritize problems, and to plan the deployment of limited resources (for example, redeploying staff to triage or treatment centers or readying hospitals to receive casualties). This involves diverse professions (medical staff; public health officials; emergency response teams; biological and radiological experts; emergency management officials; municipal agencies; and private organizations responsible for transportation, communications, medical services, disaster assistance, and public works construction) collaborating to access, interpret, collate, and use information to manage medical crises. Team development activities are required to develop the capability of such teams to utilize their collective expertise, even if dispersed (as when operating in remote triage or treatment centers) or contributing different perspectives, to facilitate the deployment of doctors, nurses, paramedics, and others operating at the front line to meet the medical and health needs of survivors.

Frontline Response

Crisis response results in medical staff having to apply their professional, technical, or scientific skills in atypical, challenging, and threatening circumstances. Operational staff (doctors, nurses, emergency medical technicians) may be functioning in a hospital environment or they may be working in remote locations with varying degrees of access to resources and facilities (for example, remote, temporary hospital facilities set up in a town hall). They may be performing their normal roles, or they may be reassigned to nonroutine roles such as communicating with the public, disaster triage, or body identification. Disaster triage illustrates how working in disaster contexts can result in familiar tasks taking on an unfamiliar guise.

Triage during a disaster differs from that performed in routine prehospital and hospital settings. The number of people to be treated is greater, and the availability of medical resources to treat them is limited and may be absent. Consequently, patients may remain in situ for prolonged periods of time during which they will need to have their status reassessed frequently. Furthermore, triage will be decentralized and possibly occurring in several locations spread over a large geographical area simultaneously. Under these circumstances, patients who might be expected to recover under normal circumstances may experience deterioration in their condition as a result of delays in getting hospital care.

In the absence of specific crisis response training, medical staff will present with triage experience derived from situations in which definitive care is immediately available and triage required only once. Training is required to develop skills suited for making treatment decisions when access to definitive care for patients is problematic. This includes estimating the delay before definitive care will be available or accessible, and thus the time patients will require in situ care under challenging circumstances before being evacuated to the hospital. Including these additional time and assessment issues is important. The longer staff are required to treat survivors in isolation, the more frugal they must become in the use of supplies and in the selection of patients to treat. The ensuing conflict between their normal role expectations and the demands of crisis response can be a significant source of stress.

Because it can have a profound impact on staff performance and well-being, managing psychological stress in frontline staff is an important component in an effective operational response. This can be done through staff monitoring, support, and counseling services and through training covering, for example, surveillance, diagnosis, reporting, emergency patient care (risk assessment, planning, response roles, and communication), and public health emergency preparedness. Staff education and training promotes better understanding of risk, enhances knowledge, and increases the ability of medical staff to function safely and effectively in a crisis.

Heat Waves

Heat waves are extended periods of abnormally high atmospheric temperatures and humidity extending from more than one to several days. They are also referred to as extreme heat events (EHEs). EHEs are a global phenomenon that affects both developing and developed nations. There have been more incidences of EHEs in the last two decades because of the global warming phenomenon, which has given rise to a number of climate extremes, including floods, drought, heat waves, and many others. Heat waves are more pronounced in densely populated areas because of urban heat island effects.

Over the last few years, there have been high mortality and morbidity cases in various parts of the world resulting from heat wave episodes. An estimated 35,000 deaths were recorded in Europe during the 2003 heat waves, with 15,000 of the deaths being in France. In 1998, over 2,000 deaths were recorded in a heat wave episode in the Orissa and Andhra Pradesh areas of India. Similar numbers of deaths were also recorded in Athens in 1987. An estimated 692 deaths were recorded in Chicago, with over 3,000 sent to the emergency room in 1995 heat wave episodes.

Extreme heat events can result in a severe crisis from the potential impacts on human health and an increased burden of mortality. During EHEs, there is a slowing down of the evaporation of body perspiration that helps cool the human body. The body then has to work harder to maintain a normal body temperature of around 98.6 degrees F. When the thermoregulatory system fails as a result of excessive heat, it results in various heat-related illnesses such as heat stroke, heat exhaustion, heat fatigue, heat syncope, and skin eruption. Most EHE-related deaths are caused by heat stroke, where extreme body temperatures above the healthy limit lead to damage of the thermoregulatory system and body cells. It can result in confusion and, in some cases, unconsciousness. The complications that can result from heat stroke include kidney failure, liver failure, disseminated intravascular coagulation, and respiratory distress syndrome. It can also contribute to thrombogenesis and interfere with hypertension treatment. Heat exhaustion is also very common and in most cases precedes heat stroke. It is often characterized by dizziness, fainting, and headache.

Heat waves pose serious health risks to all categories of people. However, certain categories are more exposed and vulnerable to the impacts of heat waves. They include infants and children up to 4 years; elderly people aged 65 and over; overweight people, because of the tendency of their bodies to retain heat; diabetic people; and those with heart and blood pressure conditions. Other groups of people who are also very vulnerable are people confined to bed and who are unable to care for themselves; people on medications such as anti-inflammatory drugs, neuroleptics and antidepressants, beta-blockers, sulfonamides, benzodiazepines, and a host of other medications that aggravate dehydration. EHEs can also cause crisis-level weather conditions like drought, which can impact crops and put stress on livestock and pastures.

Crisis Response

During heat wave episodes, the responsible government organizations and crisis managers have a role to play in alerting people about what to do or not to do in order to avoid the effects of EHEs. This helps influence the behavior of the public during the episode and helps in reducing potential mortality rates. Certain countries like France and Italy have now developed action plans for managing EHE episodes. These include alert systems for health warnings, providing advice to the population, and activating the social and health care networks.

Crisis managers should put mitigation strategies in place to reduce the impacts of EHEs and the associated burden of mortality. Mitigation strategies include a health heat warning system that uses weather forecasts. Communication of warnings, where applicable, should use a community-based approach to ensure that very vulnerable people like the elderly are reached. Reliable heat stress indicators should be identified by managers or other responsible authorities one to two days in advance to give enough time for the activation of an emerging plan.

The health heat warning system should take into account the threshold above which potential health effects set in, as different populations respond in different ways when exposed to similar weather conditions. The thresholds are often derived from statistical studies of relationships between mortality rates and weather conditions like temperature and humidity. They can also be derived from biometrological studies. When threshold limits are forecast to be reached or exceeded, the activation of the warning system is required. Responses should ideally be tiered or multistaged. This allows for adequate time to weigh the risk to public health and determine an effective response approach.

During EHEs, managers and authorities should provide specific advice to the public on how to recognize the problem and how to protect themselves and other people. Generally, the public should be advised to keep cool and increase their intake of fluids (nonalcoholic). People under instructions from their doctors to limit fluid intake should check with their doctor on how much they can take. People should also reduce physical activities, avoid alcohol, stay indoors and take frequent cool showers. Outdoor activities should be scheduled for morning and evening hours when the temperatures are relatively lower. Lightweight, light-colored, and loose-fitting clothing should be worn.

High Reliability Organization Theory

High reliability theory's (HRT) central assumption is that organizations existing within complex social, political, and technical environments can perform at highly reliable levels. In the 1980s, scholars disputed the idea that high risk organizations (HROs)—those in the nuclear, electricity, health care, and transport industries—were fertile grounds for disaster. Their objectives and what ultimately became their theoretical foundations were to examine high risk organizations to determine the behavioral components that limit accidents from occurring. Otherwise known as the Berkeley group, these scholars recognized three organizations in the United States distinguishable for their record of reliable performance: (1) the Federal Aviation Administration air traffic control system; (2) the Electronic Operations and Power Generation Departments of PG&E, including the Diablo Canyon nuclear power plant; and (3) the peacetime flight operations of the U.S. Navy's Carrier Group 3 and its two nuclear aircraft carriers. Together, the examination of these organizations laid the groundwork for the high reliability framework.

Later, theorists such as Karl Weick and Paula Consoloni contributed to HRT's premises. High reliability organization theory and HROs are distinguished against Charles Perrow's Normal Accident Theory, which focuses on how an organization is structured and suggests that crisis triggers are inevitable, or "normal," in complex, tight-coupled technological systems.

In particular, Karl Weick's notion of mindfulness and group cohesion is arguably his major contribution to the theory. Focusing on the notion that HROs continuously must deal with the unexpected, and therefore know how to react, Weick argues that HROs must deal with the unexpected rather than ignore it, because failure to do so can be fatal. Five identified ways in which HROs operate that help them cope with the unexpected are preoccupation with failure, reluctance to simplify interpretations, sensitivity to operations, commitment to resilience, and deference to expertise. However, it was the Berkeley group—with their emphasis on political science, engineering, psychology, and business—that made the contention that organizations can be free of human error as long as humans exert the effort to remain error free. They outlined the following strategies as ways for organizations to operate on a safe and reliable level.

Redundancy

Organizations that are complex and tightly coupled can perform at their highest levels when personnel, technical components, or operators back up failing parts or others' failures to perform a task. One notion of redundancy is that the probability of consequential failure is reduced when this strategy is properly enacted. For this strategy to work, HROs must coordinate communication at all levels. Organizational leaders must make it a goal to put safety first and disseminate that goal to interdependent departments. HROs must also strive for balance and be prepared to engage in decision-making processes that are dynamic and interchangeable. Thus, individuals at all levels of an organization must be open to the notion that accidents can occur and be educated on how to fix potential problems. High levels of redundancy enable individuals to reorganize, restructure, and rethink their activities. Others would argue that organizational members should focus less on decision making as a possession and more on the flexibility of sensibleness. Thus, the act of sensemaking also enables organizational members to rework original safety contentions and adapt to unforeseen situations that can have disastrous consequences. However, such balance must also be sustained, and along with high levels of redundancy there also needs to be a culture of reliability.

Culture of Reliability

Creating a culture of reliability involves a continuous and decentralized practice of operations. Those in leadership positions must be able to rely on the decision-making authority of every member of the organization. Interruptions can occur at any time, so it is imperative to be flexible to changing conditions. Certain conditions can occur within an organization (such as system breakdowns, technical failures, or disgruntled personnel); however, social conditions can also affect the performance of an organization. Thus, organizational leaders—in order to sustain balance—must be able to anticipate such conditions while creating a resilient frame of reference for all members.

Recognizing anticipated hazards can impede one's ability to make informed decisions; however, creating a culture of resilience and acknowledging the inevitable can also reduce impending and often unexpected dangers. Thus, the entire organization must be able to create something reliable out of unreliable parts. Giving members of an organization the autonomy to react to intricate and complex interactions instills a sense of competence and enables members to correct tightly coupled processes before they become problematic. Thus, routinization is not a goal; instead, variations in organizational practices are key to challenging employees and creating a resilient and reliable culture.

Conceptual Slack

In order to avoid undue or uninformed actions, organizational members can apply a strategy otherwise known as "conceptual slack." Conceptual slack is the idea that decisions regarding technology and production processes are negotiated and discussed between interdependent members before a course of action is taken. This strategy works best when a system is loosely coupled or when an organization has enough time to be able to work through potential safety premises or procedures. Conceptual slack can also occur in a hierarchical or linear fashion; it can take formal or informal relational forms and can build solidarity, trust, and credibility among organizational members. This can occur through socialization, training, and the initiation of sensemaking in new, updated, and modified ways.

It is a human tendency to normalize an unexpected event in order to ease one's tensions. This is part of a larger tendency to seek confirmation for an original belief and disconfirm that anything is wrong. Mindfulness can also be applied to the concept of conceptual slack. Mindfulness refers to the organization's infrastructure—all of its members thinking through processes that will have an error-free outcome. Thus, mindfulness acts as a mediator between the following processes: (1) preoccupation with failure, (2) reluctance to simplify interpretations, (3) sensitivity to operations, (4) commitment to resilience, and (5) underspecification of structures and the capability to discover and manage unexpected events. Conceptual slack is also a strategy that can enhance organizational learning. Similarly, mindful updating is a focus on failures, resiliencies, or other small changes that occur within the day-to-day operations of the organization. Thus, the goal then is to detect the warning that danger is present and then to become aware of the unexpected and work to contain the unexpected when it surfaces, all of which contribute to conceptual slack.

Organizational Learning

Organizational learning can occur through trial and error, although error is not recommended in high risk organizations such as nuclear power plants or power grid companies. Maximizing challenges and variety in continuous operations is one way to enhance learning, although critics believe that it is impossible to engage in such an activity because of the cataclysmic consequences of mistakes. Critics of HRT also contend that it is too difficult for HROs to engage in trial-and-error learning because error-free consequences only exist in training. However, organizations can insist on training employees by creating simulated models designed for failure. Also, organizational leaders, by creating a culture of resilience and reliability, can instill a sense of urgency and determination in their members toward reducing and managing risks. Sociotechnical systems require a standard of performance, and thus learning is not a static state; it takes constant training and understanding of the internal operations of an organization and its social environment to remain error free. Learning is also a cognitive process, one that requires the formation of new schemas and new ways of conceptualizing organizational typologies. Thus, products, people, and particulars of organizing are apt to alter and progress as humans enact problem-solving activities. Every new schema that results from this process is learning taking place.

Hijackings

Hijacking is the unlawful seizure of an aircraft by an individual or a group. It is generally associated with terrorism, although some hijackings have been carried out by criminals for personal gain. The intention is to use the crew and passengers as hostages, occasionally to obtain some financial reward but more often to obtain some kind of concession from a government or governments. The concession varies from highlighting the grievances of a particular community to demanding the release of prisoners.

Key Aviation Conventions

Three conventions are relevant to the hijacking of aircraft. The 1963 Tokyo Convention relates to acts that might jeopardize the safety of persons or property on board a civilian aircraft while in flight or otherwise engaged in international air navigation. The 1970 Hague Convention, the Suppression of Unlawful Seizure of Aircraft, deals specifically with the hijacking of civilian aircraft in flight and provides guidelines for what is expected of governments in dealing with hijackings. Finally, the 1971 Montreal Convention, the Convention for the Suppression of Unlawful Acts Against the Safety of Civil Aviation, covers attacks on, or sabotage to, civilian aircraft either in flight or on the ground. Jurisdiction can be exercised either by the state in which the hijacked aircraft lands or the state to which the hijacked aircraft belongs. Refusal to extradite hijackers is justified if the offense is claimed to be political, for example, if the hijackers are fleeing a repressive regime and seeking asylum, or the country seeking the extradition has the death penalty, but then the state in which the plane lands is obliged to prosecute.

Historical Hijackings: Planes, Trains, and Ships

Although the first recorded hijack attempt was as far back as 1931, hijacking only became relatively popular with the advent of various terrorist groups around the world in the late 1950s. The worst hijacking, in terms of casualties, occurred on September 11, 2011 (9/11), when 19 al Qaeda terrorists hijacked four planes but, rather than using the hostages as a bargaining tool, they used the aircraft to gain maximum publicity by deliberately flying the planes into iconic targets and thereby sustaining mass casualties; in this case almost 3,000 people died.

However, this was not the only occasion on which multiple hijackings occurred. In September 1970, four airliners, all bound for New York, were seized by hijackers belonging to the People's Front for the Liberation of Palestine (PFLP). Three of these were a TWA Boeing 707, with 149 people on board; an El Al Boeing 707, with 142 people on board; and a Swiss Air DC-8, with 155 people on board. When two of the four terrorists who were due to seize the El Al plane were prevented from boarding that flight, they promptly boarded a Pan Am 747, with 173 passengers on board. Not everything went according to plan for the hijackers. One of the two hijackers on the El Al plane, Patrick Arguello, was shot and killed by an Israeli sky marshal; the other, Leila Khaled, was subdued, and the plane landed in London, where she was taken into custody. In response to the detention of Leila Khaled, PFLP sympathizers hijacked a BOAC VC 10, with 114 people on board, three days later. With the exception of the Pan Am 747, which was flown to Cairo, the planes were flown to Dawson's Field in Jordan, where they were blown up. All the hostages were eventually freed. Khaled was freed by the British government on September 30 in exchange for the safe return of the hostages from the British aircraft.

Prior to the events of 9/11, air crew were normally expected to adopt the approved Federal Aviation Administration (FAA) tactic, which was to comply with the hijacker's demands and attempt to land the plane safely for security forces to deal with the situation. However, this was clearly inappropriate when faced with the circumstances of 9/11, where the hijackers were on a suicide mission. Instead, following that crisis, new procedures were brought in that required cockpit doors to be strengthened and to be kept locked throughout the flight. Closed-circuit television cameras allow the cockpit crew to see what is happening in the area immediately around the cockpit doors. In the event of a plane being hijacked, threats to the cabin crew and passengers will be ignored by the cockpit crew and the plane will immediately be flown to the nearest airport that has a counter-hijack capability.

Many airports have a designated area to which, if possible, the aircraft will be directed once it has landed. In order to prevent a repeat of 9/11, a number of countries have introduced plans, using military aircraft, to shoot down a plane if it is believed to be on a suicide mission, even though this would almost certainly result in the death of all the passengers onboard.

Hijackings are not confined to aircraft. In 1975, South Moluccan terrorists, seeking independence from Indonesia, hijacked a train, with approximately 50 people on board, in the Netherlands. The hijackers surrendered 12 days later after killing three of the hostages. In 1985, the *Achille Lauro* cruise liner, with 400 people on board, was hijacked by four members of the Palestine Liberation Front (PLF), who threatened to kill everyone on board if Israel did not release 50 Palestinian prisoners. After being refused permission to dock at Tartus, the hijackers killed a disabled American passenger and threw his body overboard. The hijackers were persuaded to surrender to the Egyptian authorities when the ship docked in Alexandria.

The hijacking of shipping should not be confused with piracy, where the motive is generally purely financial. Finally, reference is sometimes made to a computer system being hijacked when someone attacks it in such a way that it fails to deliver the service it was designed to, or the attacker takes control of the system to exploit it.

Historical Analogies, Use of

When disasters strike, people often search their memories for a "historical analogy"—typically referencing their memories about past disasters and how others responded to try to find a way to deal with the sense of loss and confusion that occurs following a disaster. This search for historical knowledge is shared by the public as well as disaster responders and policy makers. Disaster responders will use their collective knowledge to determine the best form of response to a given disaster; for example, where and how to enter an area that has been devastated by an earthquake without triggering subsequent damage (e.g., gas explosions, structures collapsing) and provide aid to those who are most in need. Similarly, policy makers use historical analogies to evaluate their policy options and determine how to respond to a disaster. Local, state, and federal policy makers learned of the need to change their disaster response policies after Hurricane Katrina in 2005, when it became clear that each level of government was not prepared for a large-scale disaster. People were stranded for days after the storm, suffering from a lack of drinking water and food. Poor sanitary conditions and crowding at relief facilities exacerbated exhaustion and acts of violence. Public outrage, combined with policy makers' recognition that changes had to be made in disaster response planning, led to large-scale revamping of how local, state, and federal governments work together during a disaster in the United States.

The term *use of historical analogies* refers to obtaining information on past disasters that have affected an area to better understand the probability of similar disasters striking the area in the future. Scientists and planners examine a variety of historical sources to obtain an understanding of the frequency of occurrence of past disasters, their magnitude, and the spatial extent of damage induced by these disasters. The following sections describe the use of historical records (including paleoenvironmental data) for obtaining an understanding of the types of disasters that repeatedly affect an area, as well as discuss the principle of disaster risk reduction planning. Finally, an examination of the history of flooding on the Mississippi River is provided to highlight the impacts of repeated disasters to a national and international economy and to illustrate how government agencies can use historical data to advise changes in policy and create a safer environment for their citizens.

Reconstructing Disasters to Inform Planning

Historical analogies can provide insight into the types of disasters that typically occur in a region, the frequency with which they occur, and the range in magnitude of these disasters. Records of these historical events can also be examined

Case Study: Historical Mississippi River Flooding

The Mississippi River is one of the largest rivers in the world. The river originates in the northern reaches of the state of Minnesota and runs for 2,300 miles (3,680 kilometers) through or along the borders of 10 states until it discharges in the Gulf of Mexico, near New Orleans, Louisiana. The Mississippi River watershed covers more than 1.2 million square miles (3.2 million square kilometers), draining 31 states in the United States and two Canadian provinces; it is considered the fourth-largest drainage basin in the world. Ever since prehistoric times, the river has served as a primary route for trade and commerce, as well as for growing rich crops in the alluvial soils of the river basin. In the first part of the 21st century, crops grown in the Mississippi River basin provided roughly 90 percent of the United States' agricultural exports; the feed grains and soybeans grown here comprise 78 percent of the world's exports in these resources. The barge system has been established along the river, and its port in south Louisiana is one of the largest ports in the world, in terms of the tonnage of goods that move through the system. A variety of goods are shipped through the Lower Mississippi, including chemicals, coal, coffee, edible oils, grain, paper, rubber, wood, iron and steel, and petroleum and petroleum products.

The Mississippi River is clearly a focal point for the livelihoods and lives of millions of people in the United States and also has a significant impact on international commerce. Correspondingly, when major flooding occurs on the Mississippi River that damages or destroys agricultural lands, the homes of farmers, businesses, and industrial plants, there is a significant economic impact on the region and on the world. Following damaging flooding along the Lower Mississippi in 1849 and 1850, the U.S. Congress passed legislation to have the topography and hydrography of the river delta studied, built a navigation channel in the river mouth, and developed a levees-only policy to help control floodwaters on the river.

The river already had a known history of flooding, with severe floods recorded on the Lower Mississippi in 1734, 1735, 1788, 1809, and 1825, and the U.S. Army Corps of Engineers hoped that the flood control measures it was implementing would reduce the damages from the recurrent flooding. Despite its efforts, severe flooding of the Lower Mississippi occurred in 1882, 1912, and 1913, damaging many of the levees and flooding the river valley. In response to the floods of 1912 and 1913, the U.S. Congress passed a flood control act in 1916. The act required the construction of more levees to control flooding along the river, but again the force of the river proved too great. In 1927, a severe flood resulted in the deaths of 500 people, inundation of 16 million acres, and damage to thousands of homes and businesses.

In response to the devastating flood, in 1928 Congress passed another flood control act, which ultimately led to the Mississippi River and Tributaries Project; this program incorporated channelization and stabilization of some portions of the river to increase the river's capacity to carry floodwaters without spilling over its banks or the levees. The program also increased the navigability of the river, which further enhanced the role of the Mississippi River in the development of U.S. international trade.

For the next 66 years, although the river was far better contained than it had been in the past, it continued to routinely crest its banks and top or destroy the levees. Flooding occurred in 1929, 1932, 1935, 1937, 1944, 1945, 1950, 1973, 1975, 1979, 1983, and 1993. In addition to being devastating to the people impacted by the floods, all of the floods resulted in severe economic losses to the U.S. economy. The flood of 1993, however, was so damaging that it changed the way that the Federal Emergency Management Agency (FEMA) managed disasters in the United States. Under the Robert T. Stafford Disaster Relief and Emergency Assistance Act of 1988, FEMA provided logistical and financial assistance to government agencies and individuals impacted by disasters that were declared national disasters by the president of the United States. The 1993 flood directly impacted the states on the Upper Mississippi River, flooding 75 communities, destroying 50,000 homes, and killing 52 people. On the Upper

Mississippi River, 80 percent of the levees were destroyed, and in St. Louis, Missouri, the river was 50 feet above flood stage for more than 100 days. The overall economic impact to the U.S. economy was nearly $20 billion.

The repeated history of flooding on the Mississippi River and extensive damage caused by these floods to the U.S. economy, in addition to the loss of lives, resulted in the development of the Disaster Mitigation Act of 2000 (DMA 2000). The DMA requires all tribes and local and state governments to develop a pre-disaster hazard mitigation plan (HMP) that identifies all natural disasters that are a potential threat to critical assets, such as hospitals, fire stations, schools, wastewater treatment plants, and water sources. Pre-disaster mitigation measures are identified and implemented to reduce the potential destructive force of future disasters. FEMA provides grants to assist the jurisdictions with the cost of developing and implementing the HMPs and their associated mitigation measures, recognizing that for every $1 spent on pre-disaster mitigation, $5 to $7 are spent on recovery. FEMA also encourages landowners to move homes and assets out of the floodplain and leave the river valley for agricultural production, exclusively. Although flooding continues to plague the Mississippi River, as a result of DMA 2000, there are far fewer critical assets located in the floodplain, and mitigation measures are in place to help protect the assets that remain. Correspondingly, the economic impact of flooding is less severe than it would be otherwise, and far fewer lives are lost.

to determine the type of damage typically associated with them, as well as its extent. A variety of sources can be examined to obtain information on past disasters that have affected an area. Good sources for historical data include archival sources (newspapers, magazines, newsreels), academic journal articles, and historical climate records. Researchers can also interview scholars knowledgeable about certain types of disasters, as well as residents who have lived in an area for an extended period of time, to obtain important information on the types of disasters that have occurred in an area in the past. For example, there is very good historical documentation of 20th-century hurricanes along the United States Gulf Coast, from the Galveston hurricane of 1900 to Hurricane Andrew of 1992. This information could have been used more fully to inform development plans and disaster response plans in the region, potentially minimizing the impact of devastating hurricanes such as Katrina.

Limitations of Historical Data

When historical data are used to inform planning and development decisions, it is important to corroborate evidence using as many lines of evidence as possible. Historical data can be flawed if the information was documented incorrectly, or if the equipment or instruments used to gather the original data were of poor quality or were not calibrated against a reliable/verifiable instrument. For example, caution should be used when using historical climate data for a region to determine conditions leading to past droughts, flooding, hurricanes, intensive storms, and tornadoes. Oftentimes, meteorological equipment used to measure temperature, precipitation, humidity, and wind speed and direction are poorly managed and there are many days of missing records, or the units of measurement are inconsistent. Too often, these data are still used to describe past climate conditions, and averaging is used to fill in the gaps, which can result in extreme events being missed entirely. As such, historical newspapers and archival and eyewitness accounts should be examined in an effort to verify past climate conditions leading up to or immediately following a climate-induced disaster.

In addition to concerns over the accuracy of historical records, historical data are often limited by the length of the record (often less than 10 years in developing rural areas), or the records are for a region several miles from the area in question. To fill the gap created by an absence of historical data, scientists can turn to physical evidence of past disasters that can be derived from

Skelgas
MO 4149 CX

A hog in rural St. Louis, Missouri, is rescued from floodwater during record Mississippi River flooding, July 9, 1993. A total of 534 counties in nine states were declared disaster areas for federal disaster aid, and 168,340 people registered for federal assistance. The Mississippi flood of 1993 provided a historical analogy so significant that it prompted the Federal Emergency Management Agency (FEMA) to change the way it managed disasters in America. The devastation spurred the development of the Disaster Mitigation Act of 2000.

an examination of geographic features on the landscape, as well as other forms of proxy data.

Using Geographic Landscape and Proxy Data

A range of geographic features can provide insight into past disasters that have occurred in an area. For example, the frequency of past flood events can be reconstructed by analyzing deposits left behind by the floods, such as river bars, slackwater deposits, and debris. Erosional scars and terraces carved out of the valley sediment are also indicators of past flood events, as are scars on trees. Similarly, ancient mudslides, landslides, and rockslides can be reconstructed by an examination of the physical landscape, and evidence of ancient wildfires is indicated by lenses of ash and charcoal in sedimentary deposits and as scarring in tree rings. For coastal communities, the height of ancient sea level can be reconstructed from ancient beach terraces and relict corals and correlated to past climatic conditions using a range of techniques.

It is important to recognize that different types of proxy data have different temporal and spatial resolution. For example, tree rings can be used to reconstruct seasonal and annual climate variation in a specific region extending back thousands of years, and forcing mechanisms for the climate variations can also be identified (such as sun spot cycles and volcanic explosions). Tree rings can also be used to reconstruct drought events, wildfires, and flood episodes. Accordingly, trees and tree rings can be used to reconstruct the frequency of certain types of disasters that have occurred within a region extending well beyond the length of most historical records. Tree ring data have high enough resolution (spatially and temporally) that the disaster and climate data derived from them can reliably be used to estimate the frequency with which similar disasters and climatic conditions will be repeated in the future.

In contrast, reconstructions of historic and prehistoric flood episodes from an examination of slackwater deposits on relict river terraces and floodplains are limited by the potential for evidence of ancient floods being destroyed by more recent floods, with past flood deposits literally being washed away. Additionally, the timing of past flood events is more difficult to establish using an examination of slackwater deposits because organic material must be dated using radiocarbon methods, which are rarely accurate to within 50 years of the actual event.

Despite problems with the temporal resolution of proxy data, scientists can establish a longer record of disasters that have occurred in an area in the past. This information can be used to better understand the frequency with which different disasters occur and the underlying conditions that led to them. By obtaining a longer record of past disasters, governments and planners can predict with greater accuracy the potential for certain types of disasters to affect an area in the future. Given that many disasters are induced by climate (for example, flooding, tornadoes, hurricanes, and typhoons), understanding how past climate change affected the various environments of all of the continents is critical for understanding how future climate change may affect these environments. Reconstructions of environmental conditions associated with past climates have been undertaken by multiple scientists and is too extensive a topic to cover here. However, these scientists also use proxy data to reconstruct past climatic and environmental conditions. Proxy data are used under the principle of uniformitarianism, which postulates that the relationships between climatic conditions and environmental response (e.g., precipitation, temperature, and days of sunshine required to grow certain species of plants) have operated unchanged throughout the period of interest.

Historical Data in Risk Reduction Planning

The information on past disasters derived from an analysis of historical data, and potentially proxy data, should be entered into a database and a GIS. After the historical data for all of the disasters have been recorded for an area, they can be analyzed to determine the frequency, magnitude, and extent of damage caused by the different types of disasters that occur in the area. Use of a GIS or hand-drawn maps is important for understanding how past disasters affected the historical landscape. For example, if an area is routinely impacted by flooding, one can rest assured that in the absence of water control projects, future flooding will occur in that area.

In addition to having knowledge of the types of disasters that historically affect an area, it is critical to understand the conditions that make it possible for the disaster to occur and the causal mechanisms of the disasters. To obtain this understanding, experts in various sciences should be consulted. For example, to understand the potential for an earthquake to occur in a region in the future, fault lines should be mapped relative to the regional geology and analyzed by geologists to determine how active they are, as well as to identify the shaking potential of the geologic substrate (rocks and sediments) in the region. The data derived from this analysis should be mapped in a GIS, and the information on historical disaster events in the region should be included as metadata in the GIS. With this information combined in a GIS, analysts can estimate the probability (high, medium, low) and extent of future disasters occurring in a region.

Conclusion

In the most ideal sense, historical analogies can be used to determine where it is safe to live: above flood zones, away from fault lines, and outside tsunami impact zones and areas susceptible to hurricanes, typhoons, tornadoes, and drought. However, in light of population pressure and economic pressures, it is not possible for the entire global population to live in areas deemed disaster free. Given these pressures, and the corresponding need for people to live near centers of commerce, historical analogies can be used to identify repeated disaster threats and the adaptive strategies than can help minimize risks to these threats.

HIV/AIDS Epidemic

HIV is the acronym for human immunodeficiency virus (HIV), a lentivirus that binds to cluster of differentiation four (CD4), a membrane protein of helper thymus (T) cells, which are responsible for coordinating immune responses against antigens in the human body. AIDS is the acronym for acquired immune deficiency syndrome, an infectious disease of the immune system that, left untreated, results in opportunistic infections and death. AIDS is a clinical diagnosis of the human immunodeficiency virus (HIV). A healthy individual has approximately 1,200 CD4 helper T cells per microliter of blood; however, upon HIV infection, this count decline. It is not until the CD4 count drops below 200 that an individual is clinically diagnosed with AIDS. CD4 counts below 200 substantially increase the likelihood of opportunistic infections affecting the digestive, integumentary, nervous, and respiratory systems, which may culminate in death. HIV/AIDS is not transmitted through casual contact or mosquitoes but through unprotected anal, oral, or vaginal intercourse; cutting; or sharing of contaminated needles or related products; contaminated blood products; or from mother to child during birth or following through breast milk.

HIV: From Epidemic to Pandemic

From the time that HIV was first diagnosed in 1981 in the United States among a group of previously healthy men who had sex with men, the disease has developed from an epidemic to a pandemic. An epidemic occurs when five or more people are affected by the same disease in a relatively concentrated geographic area in a short period of time. As researchers became increasingly aware of the symptoms, it soon became clear that HIV had become a pandemic. A pandemic occurs when a substantial number of people are affected by the same disease at relatively the same time in a diffuse geographic area. Today, HIV is a global pandemic that has killed more than 33 million people, with mortality in the range of two million annually.

HIV the disease remains a major challenge to development and growth in certain regions of the world. In Africa, most notably in sub-Saharan Africa, where the earliest cases of HIV were retroactively discovered, the disease has resulted in the single greatest reversal of human development in history. Today, an estimated 31 percent of all new diagnoses of HIV and 34 percent of all persons living with HIV reside in the 10 southernmost countries in Africa. Despite these staggeringly high rates of incidence and prevalence, both rates appear to have peaked in the middle 1990s, and rates of infection have declined by more than 25 percent in the region over the past decade.

For example, in Botswana, the nation with once the highest HIV prevalence rate, antiretroviral therapy coverage now exceeds 90 percent and the estimated number of AIDS-related deaths has declined by half. Similarly, Swaziland, the nation with the highest HIV prevalence at 25 percent, has also seen declines in the prevalence of HIV as 80 percent of infected mothers are now on antiretrovirals to prevent mother-to-child transmission.

While a substantial amount of public attention and resources have been dedicated to ameliorating the effects of HIV in Africa, the disease has profoundly impacted other areas of the world, particularly developing regions such as South America and southeast Asia, where commercial sex work and intravenous drug use are common vectors for transmission. In these regions, HIV was on the rise in the 1990s and the first decade of the 21st century, but the incidence has stabilized, with some notable exceptions such as Haiti and Indonesia. Globally, the largest contributing factors to the stabilization and, in some regions, decline in mortality-related HIV has been the introduction of antiretroviral therapies and comprehensive education and risk-reduction measures, most notably safer sex practices. Elsewhere, in China and India, where HIV prevalence represents less than 1 percent of the total population, surveillance, public awareness, and intervention remain critical, as a 1 percent increase in the prevalence rate would result in an additional 24 million new infections, or an approximate 40 percent increase of the total number of current HIV cases.

Conceptualization of HIV as a Crisis

Since the initial recognition of HIV, various media sources, researchers, and policy makers have attempted to frame the disease as a crisis. A crisis is a type of social change where individuals, organizations, and society face widespread exceptions over a relatively short duration. Crises often serve as focusing events for media, the public, and policy makers to pay attention to a certain problem and attempt to resolve the problem through some sort of collective action. Thus, a key component of a crisis is the relatively short duration when the exception occurs, media and the public pay attention, and policy makers are willing to dedicate time and resources to attempt to resolve the problem. Legally, a state of crisis dates back to at least the Romans, where the state could exercise emergency powers, nearly always for a short period of time, in order to resolve a problem.

Like many other purported crises, HIV, it is reasoned, must be dealt with in the same manner because if resources are not effectively allocated, the disease may cascade into a broad social problem that will threaten the legitimacy of political, economic, and sociocultural systems for a particular society or region. Although proponents of this approach may acknowledge that there is very little destruction to physical structures or resources, the same can be said of other problems such as disasters like a nuclear reactor leak, a heat wave, or a bioterrorist incident. Although the aforementioned claims provide some compelling evidence for why HIV should be conceptualized as a crisis, these approaches are generally inconsistent with traditional and contemporary conceptualizations of crisis, as they often overlook important distinctions between long-term implications of HIV.

Some of these distinctions include the importance of exception origin, speed of exception disruption, and policy consequences of crisis conceptualization. Generally, a crisis emanates from a single source of exception, resulting in a cascade of exceptions to individuals, organizations, and communities. In contrast, the long latency of HIV and the need for a critical mass of incidences to generate exceptional social change makes it problematic for members of societies to recognize the threat and take appropriate action beforehand. Although it is possible for some community members to reflect back to a point in time before the onset, it should be noted that this response is qualitatively different from that of most other crises that frequently produce responses immediately or shortly after a collective acknowledgment of the onset of social disruption. These conceptual differences are not merely arbitrary academic distinctions but represent profound policy-making consequences.

Traditionally, occasions that are conceptualized as crises result in widespread short-term media attention, a rapid influx of financial and material resources, and declarations or proclamations by politicians that are often followed by relatively short-term assistance designed to restore, rebuild, or renovate presumably what was lost as a result of the disaster. Although the relatively intense and short-term focus by media, the public, and policy makers may be modestly effective in resolving the challenges of rapid-onset, singular-origin exceptions, such an approach is largely ineffective against the challenges emanating from HIV. For example, in most crises, the physical or economic consequences are very short in onset, and health care infrastructure and resources are most likely to be challenged in the short term until additional resources can be established for those in need. In sharp contrast, the onset of HIV in a community frequently requires a sustained commitment to the development and expansion of heathcare facilities as well as additional personnel in the form of epidemiologists, case managers, and community outreach specialists. Similarly, a sustained effort by media and public officials may also be required to inform and remind the public of risky behaviors that can lead to the transmission of HIV. Without long-term commitments to infrastructure and comprehensive programs focused on economic development, surveillance, public awareness, and interventions designed to reduce transmission, HIV is likely to remain an exceptional disruption for an impacted community.

Hospital Emergency Room

A crisis can be defined as any occurrence that is perceived by an individual to serve as a direct or indirect threat. That threat can be a tangible one, such as physical harm to a person or property, or an intangible one, such as damage to business operations or a personal or institutional reputation. Crisis management in the emergency department (ED) is a methodology that prepares for, responds to, and recovers from any unusual incident that has the potential to negatively impact the normal operations of the ED and its parent health care institution. The term *crisis management* is commonly confused with risk assessment. However, the starting point of the two is considerably different. With risk analysis, the focus centers upon mitigating any potential situation or hazard that could compromise the ED. With crisis management, however, the focus is to develop an appropriate response when that unusual event happens or is likely to happen.

The ED occupies a unique position in a community. It sits at the crossroads between the pre-hospital health care environment (emergency medical services [EMS], clinicians' offices, and clinics) and the health care institution that harbors that ED. It is the traditional terminus of emergency care for all varieties of illnesses, accidents, and disasters that may befall a community, and it is the initial stabilizer of major medical/surgical conditions entering into the hospital. As such, it, as well as its physicians, nurses, and ancillary personnel, enjoys the community's respect and trust. In an era of terrorist threats, environmental catastrophes, and a fracturing health care system, it remains a beacon of safety, care, and hope regardless of one's race, ethnicity, or socioeconomic status. Therefore, for the good not only of the ED and hospital, but also for the general well-being of a community, it is incumbent upon the ED to identify potential crises and develop procedures and guidelines that will facilitate a proper response to and recovery from adverse events in such a way as to preserve its continuity of operations, maintain the confidence of the community, and ensure that a similar event will be less likely to occur in the future.

In order to manage a crisis with regard to the ED, one must first understand the full implications of what a crisis is, given the ED's position within that community's health care framework. The crisis may be categorized in several different ways:

1. Quality
   a. Acute: The event occurs abruptly, with little or no forewarning; examples: a bomb threat or a suicide in the department.
   b. Chronic: The event is occurring for a time and may threaten the ED; example: a wildfire.
2. Geographical location of the crisis
   a. Internal/institutional
      i. Intradepartmental: The crisis is strictly limited to the ED; example: the unexpected death of an infant patient.
      ii. Extradepartmental: The crisis directly and indirectly involves the entire institution; example: the unexpected arrival of a VIP as visitor or patient.
   b. External/community
      i. General: The crisis involves the entire community in which the ED and hospital reside or even a jurisdiction that is contiguous to the particular ED; example: a magnitude 6 earthquake.
      ii. Agency-specific: The crisis occurs at another agency that could seriously impact the functionality of the ED; example: closure of a mental health crisis agency for lack of funding.
3. Temporal
   a. Completed: The crisis is concluded, and response and recovery phases are ongoing; example: meltdown of a local nuclear power plant.
   b. Imminent: The crisis is tangible, and planning an appropriate response takes precedence; example: the first bands of weather from a category 5 hurricane are palpable.
   c. Active: The crisis is ongoing; example: sudden loss of power in the hospital.
   d. Remote: The crisis exists elsewhere, but it is questionable as to its relation

Case Study: Improvised Crisis Management With Hospital Emergency Staff

There are occasions where even the most comprehensive plan is insufficient. In the early morning hours of December 26, a very well-regarded, well-liked emergency department (ED) nurse volunteered to work in the ED by 0300. As she was driving in, an inebriated driver driving in the wrong direction plowed into the nurse's vehicle, killing her instantly. Within a matter of an hour or so, the ED director was notified. She immediately came in to meet with her staff, provide physical and emotional support, monitor their patient-care activities, and notify the hospital administrators. While the chief nursing officer activated a modified incident command system (ICS) directing hospital staff notification and deflecting media inquiries to the public information officer (PIO), the ED director personally contacted the entire ED staff not currently at work and began making arrangements for counselor support and critical incident stress debriefings. She served as a conduit of information between the deceased's family and the ED.

The nurse arranged for nursing staff from other EDs to temporarily replace the staff so that fellow workers could attend the wake and the funeral. In order for this new staff to function efficiently, she provided "just-in-time" training and created improvised instructional material in order to familiarize the volunteer staff with the workings of the department. After that first week, the management of the situation went from crisis to resolution as staff employees availed themselves of counseling and participated in memorial services, tributes, and a permanent dedication that were in large part developed by the director. It required two months of the director's steady leadership and organizational and communication skills to help the ED staff find closure, despite the ED director's own sorrow and sense of personal loss.

    to ED operations; example: a major meningitis outbreak in a nearby community.

4. Nature of the crisis
    a. Natural
        i. Infectious: Examples include local meningococcal meningitis outbreak or a pandemic.
        ii. Environmental: Example would include an extreme thermal event (heat wave or ice storm).
    b. Human-made
        i. Accidental
            1. Technological: Example would be a grain silo explosion.
            2. Natural-technological: A classic example is the Fukushima, Japan, earthquake-tsunami-nuclear accident triad.
        ii. Intentional
            1. Terrorism: An example would be a dirty bomb detonation.
            2. Lone perpetrator: An example could be a hostage situation.
            3. Gang-generated: For example, a gang war.
5. Duration of the crisis (presumed)
    a. Short-term: Hours to a day (e.g., fire).
    b. Intermediate: Days to several weeks (e.g., hurricane).
    c. Long-term: Months to years (e.g., severe pandemic).
6. Population affected
    a. Numbers
        i. Limited (e.g., one to several individuals)
        ii. Extensive (e.g., most of the jurisdictional public)
    b. Status
        i. VIP (e.g., presidential visit; assassination attempt)

Recognizing that the ED can be negatively impacted by virtually any crisis that happens within the department, the institution, or the community and employing the schema above as a guide allows the ED to maintain a certain degree of flexibility within a structured format. It allows recognition of situations as diverse as a suicide in an ED bathroom facility, a hostage crisis in the hospital cafeteria, a tornado strike downtown, or a botulism mass-casualty incident.

The steps that are required to manage a crisis successfully include the following:

1. Hazard vulnerability analysis
2. Policy and procedure development/review/revision
3. Education of staff and personnel
4. Crisis recognition
5. Leadership (Hospital Incident Command System)
6. Notification
7. Communication
8. Recovery
9. Debriefing
10. Restart the process

Many of these steps and activities are already in place for emergency departments, because each one must meet Joint Commission on Accreditation of Healthcare Organizations (JCAHO) disaster management requirements. However, within that framework, the success or failure of a response to a crisis will largely depend on the leadership skills of key personnel within the ED and their ability to communicate calmly and clearly to staff, administrators, the media, and the public at large. That communication must be clear, forceful, honest, and transparent to all. Any attempt to minimize or deceive can have disastrous consequences on the integrity not only of the ED but also of its hospital. Although this may be theoretically acceptable to most, the chinks in the ED armor may not be obvious until policies and procedures are tested via drills and exercises.

Hostage Taking and Negotiation

Hostages have been taken in order to seek some advantage since the Roman Empire. But it was the poor handling of two incidents, one in the United States and one in Europe, that finally brought about a more professional approach in the response to hostage taking. At New York's Attica state prison in the United States in 1971, inmates took control of the prison, taking staff hostage. In regaining control, 39 people were killed, including 10 staff. The following year, in an attack by eight members of a Palestinian group, Black September, on the Israeli team quarters at the Munich Olympics in Germany, two Israeli athletes were killed and eight were taken hostage. An abortive attempt by German security forces to free the hostages at a nearby airfield left all eight Israeli hostages and five of the terrorists dead; three survived. A German police officer was also killed. Following these two incidents, many countries identified, first, the need to train negotiators, primarily in law enforcement agencies, to attempt to bring about the release of hostages unharmed. Second, they immediately started training special units, both law enforcement and military, to rescue hostages if the need arose.

Hostages are people held against their will by an individual or a group, usually for the purpose of fulfilling certain demands. By virtue of Articles 1 and 2 of the International Convention Against the Taking of Hostages, adopted by the United Nations General Assembly on December 17, 1979, it is an offense for a person to attempt to commit an act of hostage taking or to be an accomplice in an act in which hostages are seized or an attempt is made to seize them. A hostage taker is a person who has taken hostages against their will and is threatening to commit acts of violence against them. The *stronghold* is the term given by law enforcement agencies to the premises in which a hostage taker is holding hostages. A negotiator is a person who negotiates with the hostage taker(s) for the release of the person(s) they have taken hostage.

Americans held hostage in Iran disembark Freedom One *upon their arrival at Andrews Air Force Base, January 27, 1981. In a diplomatic crisis, 52 Americans were held for 444 days from November 4, 1979, to January 20, 1981.*

Next to the overall commander, negotiators are probably the most important people in responding to a hostage incident. The priorities of the negotiator, in a liberal democracy, are to save the lives of the hostages and, if possible, to save the lives of the hostage takers and to gain intelligence for the officer in command of the incident. Negotiators are trained "to play for time" by slowing things down for four reasons. The first is to allow what is known as Stockholm Syndrome to develop. This phenomenon arose when four employees who had been held at gunpoint by two criminals for six days in a Stockholm bank in which they worked declared their loyalty to the hostage takers. Second, during the early stages, when adrenalin is high in both the hostage takers and the hostages, it is hoped that time will allow them to become more rational. Third, it is important to gain intelligence in case negotiations fail and it becomes necessary to assault the stronghold. Finally, it enables the law enforcement agencies to gain the initiative.

There is a generally recognized list of items that are negotiable. They are food and nonalcoholic drinks, cigarettes, money, publicity, and freedom for the hostages. Transport can also be a negotiable commodity, providing it does not take the hostage takers outside the law enforcement's jurisdiction. What is not negotiable are alcohol, an exchange of hostages—perhaps a more high-profile person than those who are currently held—the supply of weapons, the release of prisoners, or the replacement of a law enforcement negotiator by a civilian negotiator.

Negotiators are normally middle-ranking law enforcement officers; thus, they are not in command and do not make instant decisions, and any requests or demands by the hostage taker(s) are referred upward to the overall commander. Demands are a basis for trade and, therefore, for every demand made by the hostage taker(s), the negotiator is looking for a trade-off (e.g., perhaps the release of a hostage or hostages in exchange for additional publicity). If a demand is dependent on a third party, and particularly if that third party is in another country in a different time zone, that is sometimes an opportunity for the negotiator to start sowing seeds of doubt in the mind of the hostage taker(s) in an effort to bring about a peaceful solution. Should negotiations break down or the hostage taker(s) start killing the hostages, even though negotiations are still ongoing, it may be necessary for the specialist team (invariably law enforcement or military) to assault the stronghold in order to rescue the remaining hostages. The assault should be carried out with speed, using diversions as necessary.

In most cases, the management of the incident will be entirely in the hands of the law enforcement agencies or diplomats, and civilian crisis managers will have little or no say in how the operations are conducted. However, in those cases that have international implications involving the use of negotiators from specialist private companies, crisis managers should lay down clear parameters, particularly in what they are prepared to exchange for the release of the hostage(s). In some cases, this can involve large sums of money or extraordinary demands.

There have been a number of well-publicized incidents in which hostages have been seized and held in areas that are inaccessible to their country of origin. Terry Anderson, an American; Terry Waite and John McCarthy, from the United Kingdom; and Brian Keenan, who had British and Irish dual nationality, were all taken hostage in Beirut during the 1980s and held in excess of five years. More recently, Ingrid Betancourt was held for over six years by the Revolutionary Armed Forces of Colombia (FARC) until rescued, with 14 other captives, by security forces in Colombia. In such cases, negotiations are carried out at a diplomatic level or are undertaken by a number of specialist private companies that have considerable experience in such operations.

Human Trafficking

Human trafficking refers to the recruitment, movement, and delivery of people from a host to a destination state for the purpose of enslavement and exploitation. This broad definition of human trafficking encompasses various types of exploitation, such as sex trafficking, exploitative work, recruitment of children soldiers, adoption of infants, begging, and organ trafficking. The practice of slavery has been identified since Hammurabi's Code in 1790 B.C.E. However, what has changed since then is the perspective of humanity in terms of human exploitation. Thereby, the 1948 UN Declaration of Human Rights highlights that human slavery is unacceptable. Also, the Protocol of Human Trafficking in 2000 defines as illegal this type of human enslavement and exploitation.

Human Trafficking as a Global Crime

Contemporary trafficking is much more diverse and complex than the slave trade of the past, and it has a global character because every country faces this problem as a source, transit point, and/or destination for human trafficking. The end of the Cold War, globalization, free trade, and economic competition are some of the main factors that led to the greater mobility of products and people. Furthermore, unemployment; population growth; poverty; corruption; gender, ethnic, and racial discrimination; political instability; and natural disasters are some of the main push factors that can be paired with the pull factors of demand for workers, opportunities for a better quality of living, and possibilities to live in a more stable and affluent place. Therefore, demand and supply in the modern world have increased, hence making human trafficking the fastest-growing crime, with enormous profits, which are estimated at $10–$32 billion annually. Beyond the actual criminals who exploit and enslave human beings, there are plenty of legitimate enterprises and citizens that benefit by ignoring this egregious phenomenon. For instance, many people would buy well-priced clothes made by trafficked workers, or they would hire a domestic laborer to take care of their children and homes.

Human Traffickers and Their Practices

The profession of traffickers varies, and they often have high social status and education. Traffickers can be former prostitutes, military and law enforcement personnel, lawyers, diplomats, and employees of multinational organizations. Recruitment techniques vary depending on the level of victims' education, the expectations of the victims and their families, and their financial situation. For instance, traffickers recruit victims from poor families by personal contact, deceiving families that once their debt to the traffickers is paid off, victims will be free to earn their own money. Traffickers often move individuals by long routes and in cruel conditions (e.g., cargo vessels, no medical care) using every known form of transportation and, hence, they need a military-like intelligence network to successfully avoid certain obstacles such as police and border checkpoints. Their activity is often facilitated by a number of other professionals from the legitimate world, such as travel agents, hotel owners, newspaper publishers and advertisers for the promotion of their products and services, and nightclub owners. Trafficking networks often interact with other criminals to obtain falsified documents, arrange false marriages, intimidate the victims of trafficking, and launder their profits.

Trafficking rings often repatriate their profits to neutralize law enforcement, to strengthen their political influence, and to invest in advanced technology so as to intrude into the government structure of their home countries and to make their network more flexible and viable. Other traffickers use their profits to fund terrorist groups or a guerrilla movement. Traffickers often get away with their crimes because in some countries, there is no law criminalizing their practices, the extant regulation is insufficient to combat this problem, or police do not prioritize human trafficking. Even though millions of dollars have been spent in the development of programs for the prevention of and fight against human trafficking, these measures have proven inadequate to resolve this global and deeply rooted issue.

Trafficked Women and Children

Women and girls are often victimized and denied access to education, property rights, and political participation around the world. Some societies view women as tools that can be used to advance a family's economic situation, to repay a family's debt, and to provide cash for a medical emergency.

Other causes that may lead to the victimization of women and children are family homelessness, illness or death of a parent, abandonment by a parent, and alcohol abuse and violence within the family. Traffickers may also offer money to the family for the exploitation of the child or the woman and might also threaten the victims with violent retaliation in case they attempt to escape. Many of the practices that were used during the Holocaust to produce passive victims are replicated by the traffickers. Thereby, children are often maimed to be beggars, deprived of vital organs, recruited as soldiers, and occupied in certain jobs because of their small size. Trafficked women often die, become seriously ill, and/or suffer psychological damage after constant abuse, violence, and intimidation by their traffickers.

Recommended Actions Against Trafficking

Trafficking needs much more basic research in the identification of practices regarding the prevention and combating of this global crime. Media are able to make the public aware of this pervasive phenomenon through popular actors, singers, and journalists. Volunteerism and fund-raising by individuals is also significant. Thereby, people may donate clothes, equipment, and money, and they might even offer their professional and language skills to help victims/survivors of trafficking. People should report to the police human trafficking networks that may come to their attention, hence helping government agencies to uncover trafficking cases, prosecute traffickers, and provide services to victims/survivors of human trafficking.

Hurricanes, Typhoons, and Cyclones

Cyclones are organized storms that have a circular wind pattern and a defined center (also referred to as an "eye"). Such storms are fueled by energy from warm waters. Hurricanes and typhoons are two specific types of tropical cyclones. The term *hurricane* is used to refer to storms that occur in the Northern Hemisphere and east of the International Date Line (generally affecting areas in the Atlantic Ocean, Caribbean Sea, and Gulf of Mexico), while the term *typhoon* refers to tropical cyclones that originate in the western north Pacific Ocean. To be considered a hurricane or typhoon rather than a tropical depression or tropical storm, the storm's maximum sustained surface wind speed must reach at least 74 miles per hour (or 119 kilometers per hour), a level 12 in the Beaufort Wind Force Scale. Winds of this speed cause significant waves, reduced visibility, debris, and damage to both vegetation and some human-made structures.

As wind speed increases in hurricanes, they are moved from a tropical storm into the Saffir-Simpson scale and gradually into higher categories of the scale as wind speeds continue to increase. Tropical storms are those that have sustained wind speeds between 39 and 73 miles per hour. In the Atlantic Ocean, a tropical storm becomes a hurricane when its wind speeds reach over 74 miles per hour. However, it is important to remember that wind speed is not the only potential danger from a hurricane. The power of and potential damage caused by storms can also be measured by pressure ratings (in millibars or inches), size (diameter), and how fast they are moving forward.

Although hurricanes, typhoons, and cyclones can move into colder water, in general they are more likely to remain and gain strength in warmer water, largely within areas considered tropical climates. Air moving within a hurricane gathers heat from these warmer waters, fueling a process wherein some air sinks in the center of the storm and air in the storm's outer bands moves upward and rotates because of the Coriolis force (caused by the Earth's rotation). As these storms gain strength and rotate faster, their wind speeds increase, often leading to their being considered stronger and potentially more dangerous storms.

When storms move over warmer water, they can often increase in power, as was the case with Hurricane Wilma in 2005, a storm that escalated from a tropical storm to a Category 5 hurricane in just 24 hours.

With increasing numbers of people moving into flood zones along rivers and ocean coastlines, crisis management of potential hurricanes, typhoons, and cyclones has become increasingly important. These risks are further complicated by the influx of tourists into those same areas, increasing the number of people in an area that may be hit by a cyclone, including a large number that may not have experienced such a storm before or know what to do or how to evacuate. More and better information about cyclones is emerging from increasing forecasting models. Such information can potentially improve predictions about which populations will be affected, how they will be affected, and whether they should evacuate.

Even with these improved data, cyclone prediction is not perfect and not all potentially affected residents and tourists can or will evacuate; moreover, crisis management is still needed during and after these storms. Crisis and emergency managers should be aware of the latest predictive models emerging from experts like those at the National Hurricane Center (NHC) and the Joint Typhoon Warning Center (JTWC). Furthermore, these managers should be in contact not only with other crisis managers and experts in governmental agencies and nongovernmental organizations but also with private organizations, especially in areas where these private companies cover large land areas or bring in large numbers of people (such as coastal hotels that may contain large numbers of tourists).

Many problems can emerge for crisis managers in the aftermath of cyclones. In addition to emergency response and cleanup needs, in the short term, affected areas and populations may face a lack of resources as even individuals and groups who stockpiled supplies may have lost them to severe winds or storm surges. Immediate medical attention is often needed by injured people who may not be able to get to hospitals or clinics because of missing vehicles or debris blocking roadways. Many individuals and families may be without shelter or work and need assistance finding a place to stay and a source of income. In the long term, local residents often continue to face these problems because recovery may move slowly and some homes and businesses may never be rebuilt.

As with other crises, in the face of hurricanes, typhoons, and cyclones, crisis management should account for vulnerable populations such as the poor, elderly, young, or disabled. Despite the increasing amount of lead time for evacuations afforded by improved predictive models, such populations may not be able to evacuate or care for themselves after a cyclone. Knowing where members of these groups live, whether they have evacuated, and how they are prepared can help crisis managers provide better response and assistance to everyone, particularly the most vulnerable.

Immigration

Following the end of World War II, increased global mobility among people has accelerated rates of globalization to unprecedented levels. Specifically, political, economic, and personal reasons, such as the pursuit of a better lifestyle, have prompted immigrants to relocate from developing nations to seek better opportunities. Not all migrants have moved from developing to developed nations. Nearly 43 percent are migrants from one developing nation to another developing nation, thereby creating unstable demographic transitions in the developing world. In the developed world, restrictive and often racist national and subnational immigration laws in Western nations have created a climate of crisis for incoming immigrants from the developing world. However, not all forms of immigration are across international borders. According to the 2009 Human Development Report prepared by the United Nations Development Programme, nearly 740 million people worldwide are internally displaced within their own national boundaries, compared to around 200 million who migrate across international borders. Other issues of crisis in global immigration include shrinking economies and layoffs that affect migrant workers as well as a draining of knowledge, or "brain drain," of highly skilled workers from their countries of origin. However, improved cooperative agreements between nations with progressive immigration policies as well as reforms at the national level hold keys to alleviating the global immigration crisis.

Types of Crisis Within Immigration

Immigration crises can stem from various institutional (for example, restrictive government policies, both at the national and subnational levels), environmental (for example, natural disasters, climate change), illegal trafficking (for example, human smuggling), and other factors. In addition, the economic crisis of 2008 has exposed newly emerging forms of crisis that were not envisioned before. For example, immigrant workers in Middle Eastern nations, including Qatar and the United Arab Emirates, were faced with the prospect of returning to their homelands because of the collapse of the global housing market. Further, the global economic crisis impacted remittances by immigrants to their beneficiaries in developing nations. According to the World Bank, the 2008 crisis resulted in a drop of over 30 percent of the nearly $340 billion sent by migrant workers to their respective home nations. For countries such as Tajikistan, where remittances from its expatriates amount to nearly 35 percent of the nation's gross domestic product, global economic downturns can severely affect national economies depending on immigrant revenue inflow.

Government and Immigration Crisis

Since the attacks of 9/11, national immigration laws in the United States have undergone major changes, in many cases restricting immigrant inflows. Specifically, laws enacted by southern U.S. states have called into question its legal scope within the limits of civil liberties. For example, the Arizona law, S.B. 1070, signed into law by the Arizona governor, has gained international significance for its controversial monitoring and surveillance of undocumented immigrants, including sanctioning a misdemeanor charge if they are found without immigration papers. Other states, including Alabama and Georgia, have followed the Arizona model, creating a climate of crisis within their immigrant population, particularly those from Latin American nations.

Immigration and Human Trafficking Crises

Climate change has affected every aspect of human behavior, including immigration. The United Nations High Commissioner for Refugees (UNHCR) projected that by 2020, some 50 million migrants worldwide are predicted to move elsewhere in search of better environmental conditions. These "environmental refugees," as noted by the UNHCR, are bound to flee from food shortages, floods, and other environmental disasters brought in by climate change as they migrate from the developing world to developed nations. Among various regions, the largest migration stream is predicted from North Africa and into southern Europe. Worse still, governments in smaller nations on the Pacific Ocean, including the Marshall Islands and Tonga, are making long-term plans to move their citizens to other countries because of rising sea levels predicted to submerge their island nations. In addition to climate change, recent environmental disasters have displaced immigrants from their original migration routes. The 2004 Asian tsunami displaced millions around the Indian Ocean region, forcing several developed nations in the European Union and Pacific Ocean nations, including Australia and Japan, to offer urgent asylum visas to incoming refugees. For example, by March 2005, the Canadian government had placed over 1,000 applications on fast-track processing for immigrants from the tsunami-affected areas.

On July 8, 2011, a woman and her children join the thousands of refugees in the Dadaab camp in Kenya who are fleeing the drought and conflict from Somalia. The United Nations projects 50 million immigrants will be "environmental refugees" by 2020.

Illegal transportation of persons around the world, referred to as human trafficking, is one of the least discussed issues in immigration. According to a U.S. State Department estimate, around 10,000 human beings are trafficked into the United States as sex slaves every year. Russia, Mexico, and China are some of the nations where smugglers force people, often in inhumane conditions, to be transported to other developed nations. In an effort to combat the illegal immigration crisis of human trafficking, nongovernmental organizations have been helpful. Among them, the International Organization for Migration (IOM) has implemented over 500 projects since 1994 to provide assistance to over 15,000 trafficked persons worldwide. Further, in a recent study conducted by the United Nations Office on Drugs and Crime, of 155 nations surveyed on trafficking, 57 percent reported at least one human trafficking prosecution.

Impact, Definition of

In the last half of the 20th century, there were increases of 250 percent in the number of recorded disasters, 500 percent in both the number of mass-casualty disasters and the number of people affected by disaster, 1,500 percent in the cost of disasters, and 1,640 percent in insurance reimbursement as a result of disaster, according to the 2000 data compiled by the Munich Re Insurance Company. These trends have continued unabated into the 21st century. However, they are somewhat exaggerated, because in 1950 the collection of statistics on disaster impacts was rudimentary. Moreover, only direct costs were measured, whereas now indirect costs are taken into account. Nevertheless, in 60 years there have been large increases in population and accumulations of capital investment in major hazards zones, especially along coastlines subject to hurricanes, flooding, and potentially sea level rise. Everywhere, the increase in global connectivity and technological complexity has caused vulnerability to disasters to rise and thus has made impacts more profound and complex.

When disaster strikes, these are the principal categories of impact: death, physical and psychological injury, disease outbreaks and other medical conditions, destruction of property and physical damage, economic effects and impacts upon livelihoods, and disruption of normal activities. As measured in the time taken to rebuild physical structures and fully restore normal activities, the impact of a major disaster may last for 10–25 years, depending on the severity of the event, the size of the area affected, and the resources available over time for recovery. There is increasing recognition that the restoration of livelihoods and local economic activities, preferably with democratic participation in decision making (i.e., good, transparent governance), is the key to recovery from disaster.

For convenience of recognition and analysis, the causes of disasters are usually divided into five categories:

- *Natural:* such as earthquakes, floods, hurricanes, landslides
- *Technological:* such as toxic spills, chronic pollution episodes, transportation crashes
- *Social:* such as strikes, demonstrations, riots, mass gatherings
- *Intentional:* such as terrorist attacks, hostage taking
- *Compound or complex:* combinations of the above, such as "na-tech" (natural-technological) disasters

The distinctions are somewhat artificial. To begin with, natural phenomena are not necessarily inherently disastrous. As the human propensity to

Table 1 Nonquantitative classification of levels of emergency

	Incidents	Major incidents	Disasters	Catastrophes
Impact	Very localized	Generally localized	Widespread and severe	Extremely large
Response	Local efforts	Some mutual assistance	Intergovernmental response	Major international response
Plans and procedures	Standard operating procedures	Emergency plans activated	Emergency plans fully activated	Plans potentially overwhelmed
Resources	Local resources	Some outside assistance	Interregional transfer of resources	Local resources overwhelmed
Public involvement	Very little involvement	Mainly not involved	Public very involved	Extensively involved
Recovery	Very few challenges	Few challenges	Major challenges	Massive challenges

put oneself at risk is paramount, and thus vulnerability is the root cause of many natural disasters, the word *natural* is more a convenience term than a robust descriptor. Moreover, there are many process-based links between the categories. For instance, natural disasters may affect technological capital, technology may abate or increase vulnerability to natural disasters, natural disasters may affect social stability, social conditions may help incubate dissidence and thus foster intentional disasters, and terrorism has a technological component.

As Table 1 shows, there are grounds for creating a semantic classification of the size of event on the basis of its geographical extent, its complexity, the nature of the emergency response required, and the degree of involvement of public authorities and the affected population. However, the distinctions between an incident, a major incident, a disaster, and a catastrophe are purely notional: they cannot easily be quantified, and they are not accepted by all of the protagonists in this field. Moreover, other distinctions need to be added to the classification. One of these is between sudden impact events and "creeping" disasters, or slow-onset events. Among the latter, accelerated soil erosion may eventually cause disastrous damage to structures and local food production, but it may take decades to arrive at that point. The sudden-onset disasters vary according to their degree of predictability and forewarning: most earthquakes occur virtually without warning, while storms allow varied propensities for meteorological forecasting that grant lead time for preparation to meet the impact, for example, by sheltering from tornadoes or evacuating in advance of hurricanes. Nonetheless, as Table 2 illustrates, the best way to distinguish size of event is probably in relation to the thresholds of capacity to cope with it at each level of civil administration.

In causal terms, the bases of disaster impact are hazard and vulnerability, which combine to produce risk. Besides the direct cause–effect relationship of extreme phenomena that produce damage and casualties, there are various sources of complexity. Secondary hazards can be triggered by the initial impact; for example, post-earthquake fire. Thus, after the magnitude 7.3 Hanshin-Awaji earthquake at Kobe in Japan on January 17, 1995, 531 seismically induced urban fires broke out, including a major conflagration in a retail precinct. Risks may interact: for example, reservoir dams may be subject to flood, siltation, landslide, rock avalanche, subsidence, structural failure, and spillway failure hazards, in a complex combination of technological and natural causes. Furthermore, on January 11, 2011, an undersea earthquake of magnitude 9 caused a tsunami and nuclear radiation release disaster in eastern Japan, killing 22,600 people and severely damaging or destroying 218,000 buildings. The Tohoku earthquake, or Great Eastern Japan Earthquake and Tsunami (GEJET), focused international attention on cascades, or chains, of causality. In a country where antiseismic construction is the norm, the earthquake itself had limited impact: indeed, it may have killed as few as 100 people. However, time will tell whether the tsunami (and

Table 2 Thresholds of capacity to deal with impacts of various sizes

Local incident	Local response
Threshold of local capacity	
Small regional incident	Coordinated local response
Threshold of intermunicipal capacity	
Major regional incident	Intermunicipal and regional response
Threshold of regional capacity	
National disaster	Intermunicipal, regional, and national response
Threshold of national capacity	
International catastrophe	Intermunicipal, regional, and national response, with more international assistance

associated persistent economic effects) or the contamination of several prefectures with radiation will be the most enduring legacy of the disaster. No matter how large the catastrophe, impact is always primarily local, but as a result of economic linkages, the implications may be international or even global. Hence, GEJET disrupted industrial production in Europe, where components were manufactured for Japanese industry.

One measure of the impact of disaster is its cost in terms of gross national income (GNI). In Japan, comprehensive cost estimates for GEJET suggest that it could reduce GNI by 6 percent, although the effects would be spread over a period of 6–10 years. Normally, in highly developed countries, disasters do not cost more than about 0.2 percent of gross domestic product (GDP). By contrast, in poor countries they may absorb 20 percent or more of GDP. Nonetheless, scenarios for a modern repetition of the 1923 Kanto earthquake with a major impact on Tokyo have suggested that up to half of Japanese GDP could be lost, with knock-on effects around the world financial markets. Such estimates have been criticized as exaggerated. Nevertheless, there is no doubt that insurance, one of the paramount means of transferring risk, does not have a large enough global pool of capital to amortize the effect of a really large catastrophe such as that envisaged in the Tokyo earthquake scenario. Even in the United States, it has been estimated that the National Flood Insurance Program is short a billion dollars with respect to potential losses if epochal floods were to occur.

The context of risk and vulnerability can transform an incident into a disaster or a disaster into a catastrophe. This observation has distinctive connotations for the impact of terrorism. Relatively few people are directly involved in terrorist outrages, but the impact of disruption leads to high costs for society and economic activity. For example, the cost of security has risen from 6 percent of running an airport in 1995 to around 38 percent in the 2010s, regardless of whether terrorist attacks occur or not. Another particular context is that of business continuity management (BCM), in which the impact of an incident or disaster is measured in terms of both physical damage and disruption, on one hand, and potential damage to a firm's reputation on the other. Hence, BCM deals with managing both the incident itself and the communication problems involved with protecting reputation (and thus also, for example, the stock market price of a firm's shares). Terrorism and BCM are two examples from among many that illustrate how context is important to the understanding of impact.

Finally, the protagonists of the United Nations' International Strategy for Disaster Reduction (UNISDR) have worked hard to shift the global emphasis from responding to disasters to reducing and preventing impacts by mitigation. This is the basis of its Hyogo Framework for Action, 2005–2015, whose main priorities include the enhancement of warning processes, the creation of a culture of safety and resilience, the promotion of measures to reduce underlying disaster risk factors, and the strengthening of prior preparedness at all levels. Despite this important endeavor, and whatever strategy succeeds it after 2015, much work needs to be done to shift the balance from the current heavy emphasis upon responding to disasters to one in which preventing and reducing impacts is paramount.

Specific Ways to Consider Impact

Despite attempts to shift the emphasis from response to prevention, there is still a very obvious need to consider impact from the point of view of crisis management. The resources needed to respond adequately to a disaster will be proportional to its severity, complexity, and geographical extent. The difficulties inherent in the response to disaster are a function not only of the nature of the event but also of the degree of prior preparedness, including planning, training, and exercising. Emergency response involves personnel, equipment, consumable supplies, communications, vehicles, and command structures. It requires organization, plans, and standard operating procedures designed to cope with exceptional contingencies. In some respects, from the point of view of the crisis manager, a crisis is merely an interval of time distinguished by the accelerated consumption of goods and services, but in other ways it is a critical period in which everything possible must be done to reduce adverse impacts on human health, society, and economic activities.

Impact Analysis

An impact analysis is used primarily when “change” occurs. For crisis management teams (CMT), this means performing an impact analysis—both perceived and hypothetical—to determine the impact of a crisis or disaster. A crisis/disaster is the biggest change that any individual, community, or corporation can experience. How and when is an impact analysis performed, and what aspects need to be considered by the CMT?

The first impact analysis performed by a CMT is usually at the outset or discovery of a crisis. Immediately upon being formally notified of the situation, the team must uncover and determine what the impacts are—both positive and negative, real and hypothetical—on the following:

- Departments/divisions
- Business processes and operations
- Technology systems (information technology [IT] infrastructure)
- Facilities
- Finances/financial institutions/fines
- Vendors/partners/suppliers
- Employees
- Regulatory/legal requirements
- Long-term ramifications
- Service level agreements (SLA) (contracts)
- The general public (for public relations)

Often during a crisis, the impacts of a decision are determined regarding how to immediately resolve, mitigate, or respond to a specific situation,

Case Study: Impact Analysis During the August 2003 Northeast Blackout

The great northeast American blackout of August 2003 is known around the world, among corporations and communities alike. It is known as a defining moment in business continuity, disaster planning, and emergency response processes. Some were able to weather the power outage, and many others were unable to respond effectively.

One such corporation—a leading human resource service provider in Canada—experienced the blackout just like many other corporations, yet when performing an impact analysis with its crisis management team (CMT), it was able to manage the situation and continue operations without missing a single submission deadline.

Immediate Activation of Crisis Management Plan

When the blackout occurred at approximately 4:10 P.M. on August 14, the company immediately activated its incident management/crisis management protocols, which brought together representatives from all major lines of business and senior executives using cellular phones and personal message devices that were not impacted by the power outage.

They immediately set to work performing an impact analysis of what they knew about the situation and which activities, based on the known assessment, could be implemented. The team focused on which facilities were impacted, whether operations within those facilities were operational, and which workload activities could be transferred to locations in other parts of the country that were unaffected by the blackout. Not only did they assess the impact on the nonoperational business units but also the impact on those other facilities taking on the additional workload, as these areas would need to extend business hours and ensure only critical functions were the focus.

This analysis was performed for all areas impacted by the blackout and for those that had the potential of receiving diverted phone calls, e-mails, and other core business functions that would be above their normal level of operational activity. This was performed in conjunction with technology team employees located at the other sites, as they would need to initiate many of the redirection activities because those located at the impacted sites no longer had the ability to do so.
